## SUBJECTS.

- Abortion, Criminal,** and the will to survive, 64.
- Abscess, epidural intraspinal,** of pyogenic origin, a case, W. J. Mixer, M.D., 864; Intraspinal epidural (pyogenic), case with autopsy, James B. Ayer, M.D., and Henry E. Viets, M.D., 865.
- Acidosis in diabetes mellitus,** definition and detection of, Albert A. Hornor, M.D., 148.
- Acute Psychoses of war,** 895.
- Adolescence, occupation and health in human types in the period of, 649; Mental pitfalls of, Henry R. Stedman, M.D., 695.**
- Aimen,** tests for, 138.
- Air Passages,** vasomotor disturbances of the, the diagnosis and management of, J. Goodale, M.D., 181.
- Alcohol,** the action of, 208; The effect of, on the rate of discharge from the stomach, L. T. Wright, M.D., 627; Mortality from war and, 692.
- Alcoholism,** relation of epilepsy to, Hale Powers, M.D., 64.
- Alveolar Osteomyelitis,** the present status of, its causes and treatment with vaccines, Leon S. Medalia, M.D., 367; Pyorrhea alveolaris and its treatment, 391.
- Amebic Dysentery,** peripheral neuritis following emetin treatment of, A. R. Kilgore, M.D., 389.
- American Association for the Prevention of Infant Mortality,** meeting of, 505.
- American Committee for Medical Preparedness,** 102.
- American Public Health Association,** meeting of, 505.
- American Red Cross,** hospital units, 53, 11; Appeal for aid, 68; Instruction to chapters, 68; Nursing service, 247; New bureau in New York, 653.
- Ammonium Sulfate in pollomyelitis,** Beverly Robinson, M.D., 773.
- Anastomosis** without skin flaps, 428.
- Anaphylactic Proteins,** preparation of vegetable food proteins for, R. P. Wadehouse, 195.
- Anaphylaxis,** its relation to asthma in children, Fritz B. Talbot, M.D., 191; Protein extracts in states of hyper sensitization, Horace M. Baker and Cleveland Floyd, M.D., 199; Relation of idiosyncrasy to cow's milk to, Fritz B. Talbot, M.D., 499.
- Anatomic Form and posture,** important factors in the treatment of pulmonary tuberculosis, Joel E. Goldthwait, M.D., 881.
- Anesthesia,** Edward L. Young, Jr., M.D., 22; Ether, H. H. Amsden, M.D., 322.
- Animal Transmission of human diseases,** 510.
- Anticancer Cells,** J. McLaughlin, M.D., 587.
- Anti-Flag-Cholera Serum,** new method of making, 179.
- Anti-Tuberculous Movement in Massachusetts,** the history of the growth of the, and the lessons to be learned therefrom, Vincent Y. Bowditch, M.D., 847.
- Anti-Variolous Serum,** hospital of, 68; Same, B. Woodward, M.D., 694; Jassica L. C. Henderson, 694.
- Apologia pro vita sua,** the general practitioner's, Andrew F. Downing, M.D., 17.
- Apraxia,** more reports of, 139.
- Army Medical Corps examination,** 658; And navy, the need of psychiatrists in, 803.
- Arseno-Benzol Treatment,** intravenous, report of the clinical symptomatology and laboratory findings in three cases of general paresis under, G. E. Mott, M.D., and S. M. Bunker, M.D., 238.
- Arthritis, Acute,** experimentally produced by intravenous injections of the staphylococcus pyogenes, E. C. Steinhafer, M.D., 59.
- Artificial Heliotherapy,** the mercury-vapor-quartz light a valuable therapeutic agent, John Bryant, M.D., 600.
- Asthma in Children, II,** its relation to anaphylaxis, Fritz B. Talbot, M.D., 191.
- Ataxic Paralysis,** a review of 127 cases of, G. H. Fisher, 99.
- Auricular Standstill,** an unusual effect of digitalis on the heart, with especial reference to the electrocardiogram, Paul D. White, M.D., 233.
- Australia,** venereal disease in, 577.
- Autopsy,** the psychological point of view and, Francis H. McCrudden, M.D., 167.
- Baldness** the hospital cottages, 547.
- Bare Hospital Units,** American Red Cross, 32, 211.
- "Better Doctoring for less money,"** correspondence on: A medical of medical ethics, H. P. Greedy, M.D., 70; A general practitioner's opinion, Frank E. Bateman, M.D., 251; Is it worth while? Robert T. Edes, M.D., 260; Hospital and general practitioner, Frederic J. Corton, M.D., 432; Better doctoring for less money, Stephen R. Ashmore, M.D., 431; The general practitioner's "apologia pro vita sua," Andrew F. Downing, M.D., 17.
- Biochemistry,** progress in, A. Everett Austin, M.D., 639.
- Blind Control,** moving picture about, at Boston theatre, 61.
- Blind Hates,** declining, 432.
- Blinded Soldiers,** the future of, 435.
- Blood, pressure, low, shock and, 873; Sugar in diabetes mellitus, observations on, Orville F. Rogers, Jr., M.D., 152; Transfusion in the great war, William R. Eldred Morrison, M.D., 629.**
- Bloody Tears,** a case of, M. J. Konikow, M.D., 607.

- Mercury-Vapor-Quartz Light** as a valuable therapeutic agent, artificial heliotherapy, John Bryant, M.D., 600.
- Metabolism**, pancreas and, in diabetes, speculations regarding, Hugh P. Greeley, M.D., 753.
- Mexican Situation**, medical aspects of, the, 28.
- Military Medicine**, course in, at Harvard Graduate School, 61.
- Milwaukee County Medical Society**, meeting of, 505.
- Miscellany**: The pay consultation clinic at the Massachusetts General Hospital, 33; American Red Cross preparations, 51; Red Cross appeal and instructions, 48; resume of communicable diseases for 1918, 169; communicable diseases for June, 142; The fly problem, 115; new method of making anti-hocholesterol serum, 179; United States medical reserve corps, 180; fraudulent infantile paralysis "cures", 218; prevention of poliomyelitis, 219; instructions to field workers regarding procedure for the control of poliomyelitis, 220; the Lihlenfeld x-ray tube, 132; declining birth rates, 432; resume of communicable diseases in Massachusetts for August, 1918, 169; annual transmission of human diseases, 510; the story of the Back family, a study in dysgenics, 512; the sanitary progress and vital statistics of Hawaii, 516; Ears visible in hospital cottages, 517; occupation and health in adolescence, 518; health insurance, 519; an instance of medical heroinism, 519; resume of communicable diseases for September, 1918, 618; army surgeons as military commanders, 620; American Society for the Control of Cancer, 651; competitive examination for state epidemiologist, 735; State Department of Health, 735; Massachusetts State Department of Health, communicable diseases for October, 1918, 619; United States civil service examination, 810; the fact of 1918, 810; No. 10151, 810; tendencies in health insurance legislation, 921.
- Harford, Dr. William W.**, 245.
- Mosley**, necrology, 245.
- Motion Study** for more efficient operating, 165.
- Mount Sinai Hospital**, memorandum in relation to the proposed "line for paying patients" to be conducted in collaboration with a group of specialists, 596.
- Murphy, John Benjamin**, M.D., death of, 278. Obituary, 810.
- National Board of medical examiners**, 191.
- Navy** as a field for medical work, 689; Health and sanitation in, 87.
- Necrobacillus Infections**, exfoliative dermatitis following, Rene Bino, M.D., 96.
- Nephritis**, tests of renal function from the standpoint of the general practitioner, Francis W. Peabody, M.D., 158; Eye changes in renal diseases, their diagnosis and prognostic value, Peter Hunter Thompson, M.D., 161; Discussion, 161.
- Neuritis, Peripheral**, following emetin treatment of amebic dysentery, A. R. Kilgore, M.D., 380.
- Neurosyphilitic Affections**, syphilitic and in war, E. Reed, M.D., 51.
- New England Surgical Society**, 575.
- Noxocaine Addiction**, the possibility of, 507, 615.
- Obese**, circulatory disturbance in the, Clifton L. Buck, M.D., 332.
- Obesity**, treatment of, by a rational diet, Edward E. Cornwall, M.D., 601.
- Obstetrics**: Cushing, Ernest Watson, M.D., 357; Gay, Warren Fisher, M.D., 559; Murphy, John Benjamin, M.D., 810; Stone, Eugene Potter, M.D., 431; Lincoln, David, Francis, M.D., James J. Putnam, M.D., 693; Willis, Reuben, M.D., 431; Woodbury, Louis Augustus, M.D., 11.
- Obstetric Report** of progress in, Robert L. De Normandie, M.D., F.A.C.S., 567; Treatment of weak labor pains, Stephen Rushmore, M.D., 659.
- Occupational Diseases**, certain occupations as contributing factors to diseases of the skin, Charles J. White, M.D., 35; Occupation and health in adolescence, 518.
- Oppenheim's** new disease of children and young adults, dystonia musculorum deformans, Isador H. Rubin, M.D., 43.
- Ophthalmology**, progress in, Edmund W. Clap, M.D., 798.
- Orthopedic Surgery**, eleventh report of progress in, Robert L. Good, M.D., Robert Scatter, M.D., Hermann Bucholz, M.D., Harry C. Low, M.D., and Murray S. Danforth, M.D., 369, 342.
- Oxygen**, insufficient, as a factor in disease, Francis H. McCradden, M.D., 480.
- Pancreas and Metabolism** in diabetes, speculations regarding, Hugh P. Greeley, M.D., 753.
- Parasitis**, treatment of, by intra-ventricular injections of diarsenofol serum, with presentation of cases, Philip Coombs Knapp, M.D., 24; General report of the clinical symptomatology and laboratory findings in three cases of under intravenous arsenobenzol treatment, G. E. Mott, M.D., and S. M. Parker, M.D., 338.
- Parker, William**, Thornton, M.D., 243.
- Patella**, operative treatment of fracture of the, Charles L. Scudder, M.D., and Richard H. Miller, M.D., 111.
- Peptic Ulcer**, a study of, from the diagnostic point of view, R. H. Philbrick, M.D., 121.
- Peripheral Neuritis** following emetin treatment of amebic dysentery, A. R. Kilgore, M.D., 380.
- Peruvian Customs**, a Horace Giraldi, 395.
- Pericarditis**, the occurrence and diagnosis of, Edwin A. Locke, M.D., 590.
- Physicians and the income tax**, 952.
- Physically Defective**, the, Edward O. Otis, M.D., 737.
- Physiological point of view and autopsies**, Francis H. McCradden, M.D., 167.
- Pistol-Shot Wound** of the stomach, Charles A. Atwood, M.D., 136.
- Pneumonia, Embolic**, following the mastoid operation, George L. Richards, M.D., 206.
- Poisonous Drugs** by Mail, shipment of, Kern-Doremus Bill, 390.
- Poliomyelitis**, epidemic, the symptomatology and diagnosis in the acute stages, Francis R. Fraser, M.D., 82; The X virus, 101; Prevalence of, 157; Epidemics of, 172, 578, 819; Progress of epidemics, 211, 218, 351, 389, 427, 507, 512, 611, 651, 690, 730, 806, 874, 819; Suggestions as to the prevention of, W. Stewart Whitcomb, M.D., 231; Symposium on, by Philadelphia County Medical Society, and the Philadelphia Pediatric Society, 238; Prevention and treatment of, 212, 219; Fraudulent infantile paralysis "cures", 218; Treatment of, 219; Instructions to field workers regarding procedure for the control, 220; Rat theory of, Mark W. Richardson, M.D., 297; Transmission of, 426; Lighter forms of, Arthur W. Fairbanks, M.D., 436; A case of, M. V. Pierce, M.D., 436; Legislation on, 166; Report of epidemic for August, 1918, A. M. Reed, M.D., and the Philadelphia Pediatric Society, in Beverly Robinson, M.D., 73.
- Post-Graduate teaching**, a new form of, 578.
- Pott, the man who potted**, Jean-Pierre David, John
- Pregnancy**, notification of, 62; Complicated with hernia, John P. Gardiner, M.D., 637; Failing cardiac compensation during, Charles H. Lawrence, M.D., 828.
- Preparedness** for health, Haven Emerson, M.D., 811.
- Proclitella**, vaginal hysterectomy for, with a report of five cases, P. E. Truesdale, M.D., 12.
- Progress**: Progress in biochemistry, A. Everett Austin, M.D., 11; Report of progress in dermatology, John T. Bowen, M.D., 19; Progress in gynecology, Stephen Rushmore, M.D., 19; Report of progress in obstetrics, Robert L. De Normandie, M.D., F.A.C.S., 567; Progress in ophthalmology, Edmund W. Clap, M.D., 798; Eleventh report of progress in

- orthopedic surgery, Robert B. Osgood, M.D., Robert Soutter, M.D., Hermann Bucholz, M.D., Harry C. Low, M.D., and Murray S. Danforth, M.D., 309.
- Proctitis**, in adults, T. Chittenden Hill, M.D., 127.
- Prosthetics**, drainage of, the mechanism of the protection afforded by the, as a preliminary to operation, Hugh Cabot, M.D., and E. Granville Crabtree, M.D., 635.
- Psychic and Neuropsychic Affections** in war, E. Regis, M.D., 784.
- Psychiatric Cases**, indications for wet packs in, an analysis of 1000 packs given at the Psychopathic Hospital, Boston, Mass., Herman M. Adler, M.D., 673.
- Psychiatric Clinic** for prisoners, 506.
- Psychiatrists**, the need of, in the Army and Navy, 803.
- Psychopathic Hospital**, the Yerkes-Bridges point scale as applied to candidates for employment at the, C. S. Rossy, 822.
- Psychoses**, acute, of war, 505; Exhaustive infective, fatty degenerative changes in the Purkinje cell belt of the cerebellum, in, Ebert W. Fell, M.D., 819.
- Purkinje Cell Belt** of the cerebellum, fatty degenerative changes in the, in exhaustive infective psychoses, Ebert W. Fell, M.D., 819.
- Pyorrhea Alveolaris** and its treatment, 391; The present status of alveolar osteomyelitis, Leon S. Medalla, M.D., 367; And its treatment, Beverley Robinson, M.D., 472.
- Rat Theory** of poliomyelitis, Mark W. Richardson, M.D., 397; Elimination of the rat, 576.
- Renal Diseases**, eye changes in, etc., Peter Hunter Thompson, M.D., 161.
- Renal Function**, tests of, from the standpoint of the general practitioner, Francis W. Peabody, M.D., 158.
- Retroversions**, the radical cure of some, an expedient for, Edward Reynolds, M.D., 830; And ptosis, 836.
- Rockefeller Foundation**, establishment of psychiatric clinics for criminals by, 506.
- Roentgenological Examination**, pre-operative in cancer of the breast, John W. Lane, M.D., 232.
- Roentgen Ray**, treatment of Graves' disease by, Malcolm Seymour, M.D., 568.
- Rosette**, in hypertrophy of the thymus gland, Philip H. Cook, M.D., 483; Some considerations on the present status of, Joseph Shohan, M.D., 321.
- Sanguineous Lacrymation**, M. J. Konikow, M.D., 607.
- Sanitation** and health in the Navy, 855.
- Scarlet Fever**, control of, D. M. Lewis, M.D., 682; The control of, F. B. Mallory, M.D., 713; Charles V. Chanin, M.D., 715.
- Secretions** of the digestive tract, a clinical study of the, Thomas R. Brown, M.D., 775.
- Shakespeare's Genius**, medical aspects of, 316.
- Shock** at the front, W. T. Porter, M.D., 554; And low blood pressure, 872.
- Sickness Survey** of Boston, Frederic J. Cotton, M.D., 112.
- Skin**, diseases of, the certain occupations as contributing factors to, Charles J. White, M.D., 355; Normal reaction of the, to stroking, Edward A. Tracy, M.D., 197.
- Social Survey**, functions of, in state hospitals, Hannah Curtis, 271; Cases, the intensive group of, Mary C. Jarrett, 824.
- Smallpox** in Roxbury, Massachusetts, 917.
- Society of Honor**, Boston Surgical Society, tenth meeting, 608; eleventh meeting, 642; twelfth meeting, 684; Essex North District Medical Society, 618; First Legislative Convention of Massachusetts Physicians, 512; Neurological Institute, clinical conference of meeting of March 11, 1916, 169; the New England Society of Dermatology and Syphilis, meeting of January 27, 1916, 741; New England Pediatric Society, meeting of Feb. 4, 1916, 237, meeting of March 3, 1916, 276; meeting of March 31, 1916, 386; meeting of April 28, 1916, 422; New England Branch of the American Urological Association, fall meeting, November 30, 1915, 644; Philadelphia County Medical Society and the Philadelphia Pediatric Society, symposium on poliomyelitis, 238.
- Soft Corn**, pathology of, Henry M. Chase, M.D., 134.
- Soft Flap**, surgical, J. B. Rieger, S.M., and H. C. Solomon, M.D., 817.
- Sprains** and sprain-fracture of the wrist joint, A. C. Burnham, M.D., 118.
- Springfield Academy** of Medicine, post-graduate classes of, 8.
- Stammering**, an outline of the elements and treatment of, Anne Bradstreet Stedman, 818.
- Staphylococcus Pyogenes**, acute arthritis experimentally produced by intravenous injections of, E. C. Steigmeier, M.D., 53.
- State Department of Health**, plans for more tuberculosis hospitals, Eugene R. Kelley, M.D., 524.
- Stone**, Eugene Potter, M.D., obituary, 431.
- Streptococcus Mucosus Capsulatus** as a cause of mastoid disease, Gorham Bacon, M.D., 602.
- Striking**, the normal reaction of the skin to, Edward A. Tracy, M.D., 197.
- Stridwick, Edmund**, an instance of medical heroism, 548.
- Suffolk District Censors'** examination, 614.
- Surgery**, motion study for more efficient operating, 465.
- Syphilis** of today, the menace of, to the family of tomorrow, J. Harper Blaisdell, M.D., 7; Contact points between pulmonary tuberculosis and, James A. Lyon, M.D., 285; Were the sailors of Columbus the first European syphilitics?, A. F. Downing, M.D., 315; Columbus and syphilis, 543; Of the lungs, Nathaniel K. Wood, M.D., 667.
- Teeth**, as a factor in the production of epilepsy, Hale Myers, M.D., 861.
- Testicle**, undescended, in children, C. G. Mixter, M.D., 631.
- Therapeutics**, teaching of, as a branch of applied physiology, E. H. McCrudden, M.D., 93.
- Thymus Gland**, roentgenotherapy in hypertrophy of, Philip H. Cook, M.D., 483.
- Thyroid Gland**, surgery of, C. A. Porter, M.D., 551; Recent advances in our knowledge of the active constituent in, its chemical nature and function, Edward C. Kendall, Ph.D., 557; Conditions affecting secretion of the, W. B. Cannon, M.D., 562; The clinical value of metabolic studies of cases, Walter M. Boothby, M.D., 564; Partial thyroidectomy with local anesthesia, scopolamine and morphia, Frank H. Lahey, M.D., 566; Treatment of Graves' disease by roentgen ray, Malcolm Seymour, M.D., 568.
- Time**, Patient in surgery, 27.
- Transuducal Bands**, congenital, a study of the symptoms and treatment of, John Homans, M.D., 665.
- Traine, Paul** (Army surgeons as military commanders), 732.
- Tubercle Bacillus**, diagnostic culture of, 269.
- Tubercular Infection** in infancy and childhood, Vanderpool Adriance, M.D., 215.
- Tuberculosis**, pulmonary, anatomic form and posture of the factors in the treatment of, Joel E. Goldthwait, M.D., 88; Hemoptysis as a symptom, Frederick T. Lord, M.D., 113; Common sense and consumption, J. B. Hawes, 2d, M.D., 115; Prevalence of, in Massachusetts, J. B. Hawes, 2d, M.D., 116; Control and cure of, 174; Massachusetts (tuberculosis dispensaries and their relation to the practising physicians, John S. Hitchcock, M.D., 225; A year's work in Worcester tuberculosis hospital, Albert C. Getchell, M.D., 229; Pulmonary, contact points between, and syphilis, James A. Lyon, M.D., 285; Carriers, Charles E. Perry, M.D., 292; In adults, what constitutes clinical?, George L. Schaft, M.D., 298; Conference, third New England, Philip P. Jacobs, 395; Treatment of, in infancy, W. W. Howell, M.D., 111; Conference of the Massachusetts Anti-Tuberculosis League, 522; Hospitals, plans of the State Department of Health for more, Eugene R. Kelley, M.D., 524; Relation of the anti-tuberculosis society to the local board of health, John W. Tapper, 526; The visiting tuberculosis nurse, Mary Van Zile, R.N., 528; In rural communities, Vanderpool Adriance, M.D., 530; Some of the problems of the trustees of the Massachusetts hospital for consumptives, Arthur K. Stone, M.D., 533; The value of a program of work for anti-tuberculosis societies, Mrs. W. H. Lothrop, 535; Role of Massachusetts sanatoria, 541; Conference, the New England, 551; Investigation at Framingham, 805; The history of the growth of the anti-tuberculosis movement in Massachusetts and the lessons to be learned therefrom, Vincent Y. Bowditch, M.D., 847.
- Tumors**, oral, epulid, intra-trasinal, of two years' duration, operation, recovery, W. E. Paul, M.D., 133.
- Tunica Vaginalis**, hematocoele of the, etc., Charles M. Whitney, M.D., 51.
- Typhus Fever**, a report of three cases of, M. G. Berlin, M.D., 755.
- United States** medical reserve corps, 180; Death rates in 1915, 541; Civil service examination, 810.
- Vaccines**, autogenous, hay-fever treated by, Leon S. Medalla, M.D., 201; Treatment of alveolar osteomyelitis by, Leon S. Medalla, M.D., 367; 391.
- Vaginal Hysterectomy** for proclivita, with a report of fifty cases, F. E. Truesdale, M.D., 13.
- Vasomotor Turbances** of the upper air passages, the diagnosis and management of, J. L. Goodale, M.D., 151.
- Veneral Disease** in Australia, the regulation of, 577.
- Viscera**, Electric delineation of, 766.
- War**, effect of, on younger generation in Germany, 315.
- Wassermann Reaction**, the diagnostic significance of, 102.
- Weibel** in medicine, 403.
- Welfare Work** among industrial corporations, 175.
- Wet Packs**, indications for, in psychiatric cases, an analysis of 1000 packs given at the Psychopathic Hospital, Boston, Mass., Herman M. Adler, M.D., 673.
- White, James Clarke**, M.D., memorial address, Abner Post, M.D., and Frederick C. Shattuck, M.D., 79.

**Whooping Cough**, the measures to be taken for its control and prevention, John Lovett Morse, M.D., 723.

**Wills, Heuben, M.D.**, obituary, 131.

**Woodbury, Louis Augustus, M.D.**, obituary, 113.

**Worcester Tuberculosis Hospital**, a year's work in, Albert C. Gatchell, M.D., 229.

**Workingmen's Compensation**, medical aspects of, Francis D. Donoghue, M.D., 100; Restoring the injured employee to work, Francis D. Donoghue, M.D., 127; Hospitals and workmen's insurance, F. J. Cotton, M.D., 161; Industrial insurance and workmen's compensation, 164; A square deal to all, M. A. Tighe, M.D., and J. A. Mehan, M.D., 171; The viewpoints, W. H. Merrill, M.D., 172; First legislative convention of Massachusetts physicians, 512; A rejoinder on, William G. Reed, M.D., 550; Report on, of the Massachusetts Medical Society, 581, 686; Decision of Michigan supreme court relative to, 609; Charles Malone, M.D., 773; Workmen's sickness insurance and the doctor, report of committee of the Massachusetts Medical Society, 880; The Workingmen's Compensation Act, John C. Crosby, 883; A consideration of workmen's accident and sick-

ness insurance in their relation to the medical profession, F. J. Cotton, M.D., 893; History and operation of the Massachusetts Workingmen's Compensation law, Francis D. Donoghue, M.D., 897; Workingmen's compensation for accident and sickness, from the point of view of the general practitioner, W. H. Merrill, M.D., 902; Workingmen's compensation for accident and sickness, from the point of view of organized labor, John P. Meade, 905; Administration of the Workingmen's Compensation Act by the City of Cambridge, Massachusetts, Herbert J. Cronin, M.D., 906; Industrial health legislation, Francis W. Anthony, M.D., 911; The medical department of a modern industrial plant, F. O. West, M.D., 914; Medical aspects of social insurance, 917; The Doten Bill, its graver errors, John J. Hurley, M.D., 922.

**X-Ray Tube**, Lilienfeld, 132.

**Yellow Fever**, ancient history of, 728.

**Verkes-Bridges Point Scale**, the, as applied to candidates for employment at the Psychopathic Hospital, C. S. Rossy, 822.

### Address.

#### LEONARDO DA VINCI'S SCIENTIFIC RESEARCH, WITH PARTICULAR REFERENCE TO HIS INVESTIGATIONS OF THE VASCULAR SYSTEM.\*

By ARNOLD C. KLEBS, M.D., WASHINGTON, D. C.

HISTORY in our days is not read any more as it used to be in less skeptical ages. Scientific scrutiny is applied to its component parts as far as material is available, and every effort is exerted toward bringing to light new material. The acceptance of historical events as gospel truth on account of the sanctity or intellectual authority of the recorder is relegated to the undiscussable realm of the emotional. And still we are very far from the day of an unemotional, objective representation of historical values. An innate obstacle, a mental inadequacy in ourselves, seems to exist, which again and again makes us revert to an uncritical worship of our old heroes, great discoverers, inspiring events, no matter how much cold reflexion, or contrary scientific evidence has done toward modifying the traditional picture. This evident inability to perceive and conceive the continuity of events has been well epitomized by Bergson by comparing the mental processes involved to the chemical and physical ones of the cinematograph. By means of this much perfected modern instrument we can increase the illusion of reality with

the number of single perceptions, photographic snap-shots in this case, which we project on the screen in rapid succession. Take, for example, the film of one event; a man saves a child from the water. In apparent continuity certain phases of the action impress us more distinctly than others; the child in the water, the man throwing off his coat, the splashing of the water, his reaching the child, for example. Between these main impressive phases we overlook the intermediate lesser phases. Their significance we realize only if we cut them out and obtain a ragged, improbable, unsatisfactory representation. And still this latter is exactly the method by which history is taught and the kind we read casually. Literary style and an appeal to the imagination have to make up for the deficiency.

*A priori* one should think that in the history of scientific research, those who have recorded the successive events would be less likely to succumb to purely literary temptations. Curiously enough this is not any more true here than in the realm of general history, although we can perceive in some modern endeavors a desire to draw away from unsupported tradition. But in general, the scientist also, when entering the historical field adheres to persons, episodes, discoveries, whose importance he almost inevitably exaggerates. Very often this tends to falsify our judgment, by elevating the epoch in which we live and work into a position of perfection out of the line of continuous evolution. It is worth while to practise from time to time a little introspection as regards the validity of our stock of traditions. While we are apt to look with scorn upon the dogmas, religions and others, which

\* Paper read before the Harvard Medical Historical Club, February 1, 1916.

"La figure de l'homme." This (schematic) drawing of the male torso has an interesting resemblance to the phlebotomy figures in Ketham's *Praxis Therapeutica* (Venae, 1491, and *Praxis*, 1501). (From Lascaud de Vinci: *Notes et Dessins*, Paris, 1901.)

This sketch, better perhaps than any other, shows Leonardo's mastery in anatomical observation, artistic and plastic perception, and technique of dissection. Very likely he injected the blood vessels in that way or some other hardening substance. (From Notes at Musée, Paris, 1901.)

eagerly snatched up by the defenders of the attacked idol. The battle is still on, although the one who stirred it up has been silent since its inception and the greatest defender of Vesalius' reputation (Roth) has been called to rest. It has reached the stage of trench warfare fought with the most perfected scientific weapons, and we neutrals are reaping the benefit in the form of a vastly increasing knowledge about both Vesalius and Leonardo.

It cannot be my intention, from what I have said before, to take part in the contest, or, as you may judge from the title of this paper, to pose as a protagonist of Leonardo's cause. I have tried to acquaint myself with all the available manuscripts, of which the most important collections are in Milan, Paris and London (now published practically in their totality in excellent facsimiles, with transcription and translations) and from the insight thus obtained, superficial as it may be, I have received certain general impressions.

Leonardo's lifetime—1452 to 1519—coincides with the auge of the Italian renaissance, that epoch during which what appears to us now as the senile mediæval intellect, had rejuvenated itself in the ardent contemplation of antique works and models. On the development of art Leonardo's influence in that epoch is admittedly paramount. Art critics are, perhaps, more easily satisfied than scientific ones, for also in art Leonardo's actual legacy is not abundant. The difficulty for the scientific critic is that he has to depend so much on the criterion of the written and published work. He cannot trace historically the influence of one man or school through long periods by a visual analysis of such subtle features as technique, mannerism, drawing, composition, or modelling in the work before him. And still the critic or historian of artistic and scientific work have this in common, that their respective objects of study, while differing in the mode of expression, aim both at the representation of the truth. But "there are two kinds of truth," as Froude says in his "Origen and Celsus"; there is the general truth, the truth of the idea, which forms the truth of poetry, there is the literal truth of fact, which is the truth of science and history. But when he adds: "They correspond to opposite tendencies in human nature, and never as yet have been found to thrive together"; while admitting the correctness of the inference in general, medicine, being both an art and science, escapes, in part at least, from the odium of such generalization. The artist with an eye trained by long practice and experience to observe the slightest deviations in outline, form and color, and a hand to render with utmost accuracy not only the object before the eye, but also the impressions retained by virtue of an often tested visual memory can, if his interests lie in this direction, render the greatest assistance in a scientific inquiry. Leonardo, who did possess these qualifications to a superlative degree, not only had the interest of

the "dilettante" or the humanistic scholar, striving for universal erudition after the fashion of his day, but a passion for knowledge. At least so he appears to us as we follow his train of thought in his notes. Ever and ever he seems urged on by irresistible curiosity to ask himself questions about anything and everything that comes into his path. His notes were not written, his sketches not drawn for publication. Whatever his own ultimate designs in this respect may have been, nothing so far has appeared from his hand which bears the mark of a manuscript intended for the press. All theories in this regard are without foundation.\*

This granted, and in the absence of any comprehensive and completed statement of his knowledge, how are we to apprehend and judge Leonardo's contribution to our science? Are we to consider him merely as an interesting phenomenon devoid of any or only negligible historic significance? Or may we perhaps, hope that further research may show his direct influence on the discoveries that grace the records of scientific history? If this history once is simply written, in Osler's sense, as the biography of the mind of men, one might be hopeful that Leonardo's work would find a place; meanwhile in the juxtaposition of individual biographies now called history of science, there is no definite place for Leonardo. And still in a sense this enhances his true value, not only because of his remarkable intellectual endowment or his artistic pre-eminence, which speak out of every page of his notebooks, but because, paradoxical as it may sound, for the fact that such methods as he employed in his search, such conclusions, which they allowed him to reach, could have, and evidently did, remain hidden for more than two hundred years. Had his notes and sketches just as they were, say in 1512, been put in order and published, that book would have a very definite place in the historical annals. Does the only fact that none has appeared diminish the greatness of the mind that produced the notes, and are we entirely forgetful of the fact that mind has always bespoken mind, even before the invention of the printing press, and presumably also after and without its intervention? Surely not. Thus we see incorporated in Leonardo merely that kind of intellectual force which has asserted itself in ways difficult, sometimes impossible, to trace; a force which exists in every thinker, whether in science or in other fields, and of all ages in varying degrees. From Leonardo's notes one is allowed to learn what he has to say almost as if one were hearing his own words, watching his objects with him and his delineation of their various aspects. He expresses himself not in the obscure latinity of scientific jargon, but in the vernacular, most fa-

\* In the collection of the Uffizi at Florence, Sudhoff discovered a drawing of a heart which he attributed to Leonardo. It is a loose leaf, which he holds by a thin red thread and outside appearance, may have formed the cover of a collection of anatomic sketches put together for presentation to the woodcutting. This single sheet, even if it can be proven to be by Leonardo, is evidently no conclusive evidence in the inquiry.

miliar to him, without any consciousness of having to address anybody, spontaneous, brief mental notes, when he cannot make his sketches speak, his preferred method. He does not argue and quarrel with scientific antagonists to show his own importance, but often he does introduce by the words, "the opponent says," possible objections to his own propositions. He does not tell us any harrowing tales of his going out in the dark night to cut the body of a criminal from the gibbet, nor does he seem to have hidden putrefying extremities in his bed chamber. His interest, however, in dissection and his skill in it are apparent to anyone who will study his sketches. Opportunity for dissection in his time was much more frequent than is usually assumed. In Milan, the chief centre of his anatomical work, at the Ospedale Maggiore and the Academia dei Fisici he could find all the material needed. He never complains of lacking material (save once when at Rome he was not allowed bodies for the purpose); the only thing he was always in need of was—time, which is easy to understand, considering the demands made upon him by the Ducal Court and his many other occupations.

But while his sketches are speaking witnesses for Leonardo's full understanding of the immeasurable advantage of direct observation and experiment over that derived by mere book study, it is evident that he also consulted the authorities the same as any intelligent searcher after truth must do. The paralyzing effect of book study and the worship of authority in those days is too often exaggerated. It existed then as it exists now, and it is sometimes worth while if we remember that we also swear by Darwin, Pasteur, Koch, Ehrlich as they did by Aristotle, Galen and Mondini, for instance. In all times there are those who by reading will come under the ban of authority, while to others thought, in whatever expression encountered, will beget thought. Leonardo's epoch is often represented as that of the dawn of sober thought after a night of distempered dreams. It is not so; his span of life and perhaps the few following decades mark the apogee of a cultural period, the roots of which reach into the twelfth and thirteenth Century; and after it a rapid decline took place. During that period there had been a good deal of literary activity, original to some extent, but consisting especially in translations of Greek and Arabic texts, which familiarized the student more and more with classical works in a purer form. When we reconstruct the library of Leonardo at the hands of the authorities which he occasionally mentions, we find that their works were available in his days in excellent printed editions. Aristotle he could consult in two good Latin editions (1479 and 1496) and the monumental Greek Aldine. The *editio princeps* of Galen was available to him in a superb volume from 1490 on. Out of it spoke to him not only the voice of that great encyclopaedist of medicine, but also the experimenter,

and not least of all the wisdom of the Alexandrian school, which linked Galen directly to Hippocrates. There is no doubt that Galen gave many a hint to Leonardo, but to a man with critical acumen the question of Galen's infallibility did not even occur. Galen's anatomy and physiology, based on direct research, in human as well as in animal bodies, by dissection and vivisection, could not be ignored by Leonardo, especially since it contained some of the thoughts of Galen's greater teachers, whose words were lost. Aristotle, Protagoras, Herophilus, Erasistratus thus came to Leonardo through Galen's intermediary, just as he probably reached Avicenna, and the other Arabic interpreters of Greek thought through Mondini's little manual. Of contemporaneous literature he mentions only the anatomy of Alessandro Benedetti, as a memorandum, it may be presumed, to acquire the book, for a perusal of it would have taught him precisely little. One work, however, not contemporary, but already a good deal more than a hundred years old, was available to Leonardo in several printed editions, Guy de Chauliac's "*Chirurgia*"; its first book on Anatomy might have struck a very sympathetic note. He might have read there the following significant sentence\*: "*Anatomical investigation has to proceed in two ways, by book study and by direct observation; the former is surely useful but not as sufficient as the latter to explain clearly what can be apprehended only through the senses,*" and when further along Guy also speaks of the value of anatomical illustrations, a method which he says, already his master, Henri de Mondeville, had successfully employed in teaching. Leonardo would certainly have approved.<sup>†</sup>

But we will now examine Leonardo's method of investigation as it appears in his notebooks. As we turn the folio leaves and study carefully his sketches and the notes in mirror writing (they with a little practice become fairly easily legible) we will at once recognize certain general features which will dissuade some school anatomists from proceeding any further unless they have acquired the habit of historical open-mindedness. If they have not, they will note with painful concern the entire absence of any systematic arrangement in Leonardo's anatomy, the few descriptive notes do not sufficiently enter into the totality of observable details, and they hopelessly mix up anatomic with physiologic considerations, employing a perfectly inadequate nomenclature. The organs dissected, drawn and described are not always from human subjects, so that human and animal anatomy might again become confused, as through

\* "*Anatomia inquiritur dupliciter, una modo per librum, et trinus, quia modis licet sit utilis, non est tam utilis ad charitandum ea quae solum sensibus cognoscuntur.*"

† Leonardo mentions once the name "Gondino," which may not refer to Guy de Chauliac. The anatomy of Alessandro Benedetti is noted on one of the rare dated sheets (the date is 1508), in which year two editions of the work were published; available, other authors mentioned are Hippocrates, Galen, and Cibalino.

Gaden. There is truth in these objections, but their validity fails when we remember that we have only notes before us, made as circumstances and available material permitted observation, sort of laboratory memoranda during years of study, later mixed up during the vicissitudes which befell them after they left Leonardo's keeping. We have to put them again into their logical order, for they naturally mark stages of growing enlightenment. Without entering here into his method of delineation, it must be said that he draws simply and clearly the objects before him without any embellishments. On his pages we encounter no "rod-looking muscle-man, who with detached pendulous muscles, leans against the ruins of an ancient temple; no charming nude lady reclining upon soft pillows of a gorgeous lounge, contemplating wistfully her own navel in the opened abdomen, pictures as we see them in a hundred anatomical works from Vesalins "Fabrica" into the Nineteenth Century, pictures which certainly do not contain art to please nor anatomy to teach.

Among the great number of sheets it may be interesting to select only a few of those dealing with internal organs, which surely do not concern themselves with what may be considered artistic anatomy. And it is particularly in these studies of internal organs where Leonardo's method excelled and was so very far in advance of similar attempts so far as we know them. I will endeavor to give an idea of his study of the heart, which occupies a great number of his sheets, although it is almost impossible to do justice to it, both as to his ingenious procedure and the penetration of his mind without constant reference to all of his many sketches. For here, more than in any other field, is it necessary to see plastically, in the three dimensions, so as to understand both structure and function. Leonardo, realizing the difficulty of verbal description says: "Oh, writer, how can you adequately describe in words the entire configuration, as is done in this drawing! Your description is confused, lacking in knowledge, and you can convey but little knowledge of the true forms to the listener; and you are mistaken when you think that you can satisfy him by talking on any solid object which is surrounded by planes. Remember not to get involved in verbal explanations unless you address the blind. . . . With what words will you describe this heart, without writing a book and without confusing the mind of the hearer by the very minuteness and thoroughness of your description! You will always need another commentator or return to experience which, again being very short for anyone, can impart only a relatively restricted notion of the whole of which you desire integral knowledge."\*

The pictorial representation Leonardo gives of the heart follows two directions. In the one he draws evidently from the objects before him,

FIG. 1.—The inscription on the left sketch reads: "Vessels surrounding limits of right ventricle." This relationship is very similarly demonstrated in one picture in Heide. (from Quad. II, fol. 4r.)

in the other he schematizes. The drawings from the dissected objects—mostly bovine hearts—show his penetrating observation and also his skill in dissection. Anyone who has had experience in drawing from anatomical objects knows

FIG. 2.—Testing various shapes of valve in left ventricle when it closes up. The "X" in circle at left probably represents a wax cast of the valve. (from Quad. II, fol. 9v.)

how difficult it is to prepare the organ and place it so that the special points one wishes to emphasize and their correlations are properly brought out in the delineation. It is, I believe,

\*"Ma, e quanto più l'istituto si avvilisce alla miseria, tanto più chondoleando la mente umana, e più si è scorse aver bisogno di confronti e di ritornare a un'esperienza, e a tale in via brevissima e di notizia di poche cose resta il tutto del soggetto di che s'andri integralmente."

\*This is not a perfect translation, which suffers somewhat from the fact that in the Quad. II, p. 2 of which the original is given, the text is a little disordered, and the original is not a perfect translation.

no exaggeration to assert that, up to Henle, attempts in this direction were rather primitive. This is of interest here because in some of Leonardo's drawings we find him employing methods of representation very similar to those of Henle for the purpose of demonstrating complex relations, the coronary vessels on the heart surface, for instance, to name only one example. Also, his schematic drawings do not merit the scorn which some strictly descriptive anatomists have heaped upon them. The schema as a stepping-stone between the true image and a concept has certainly done much mischief in the historical evolution of thought, but only when considered and used by itself without verification. As a help to a clear understanding of complex objects, and especially when their component parts vary in themselves or in relation to others, as implied in the functions of organs, for instance, comprehension without a schematic representation is almost impossible. For an evolution of Leonardo's actual knowledge his schematic drawings are more important than his strictly objective delineations or his notes. That Leonardo constantly endeavors to verify and correct his schematic drawings is evident from their frequent variation. In order to enable him to do this he employs several ingenious devices aside from careful and intelligent dissection. So it appears from some of his drawings that he employed some method for hardening the heart *in toto* (Holl). For a demonstration of the relative position of different parts such a method has obvious advantage, but in Leonardo it astonishes as an anticipation of most modern technique; the same in his use of horizontal and longitudinal cross-sections at different levels of the heart to show the relative position of the ventricles. He also employs currently injections of wax or plaster to inform himself better of the configuration and the size of cavities. So he obtains casts of the heart ventricles and most instructive plastic pictures of the semilunar valves, and it is very probable that he also used wax for injecting the coronary and other blood vessels. Characteristic of his desire for exactness is the use he makes, wherever possible, of mathematics, a desideratum of scientific research to which he gives frequent expression: "There is no certainty where one cannot apply one of the mathematical sciences."\*

\* "Nessuna certezza e dove non si applicare una delle scienze matematiche che overche non sono unite con esse matematiche." This sentence from the Paris Ms. G. (fol. 96 verso, Ravaisson-Mollien) exhibits a feature frequent in Leonardo's notes and one which produces sometimes the effect of obscurity. It is the repetition in different words of the same or similar sense within one sentence. Sometimes it appears as a sort of practice in expression, an intention quite obvious on many other pages, and in his lists of words and synonyms; sometimes he seems to amplify the sense, as for instance in the phrase: "Al where he an muscles in principale di forza e de potentissimo sopra li altri muscoli." (MS. G., fol. 1, verso) a translation of which is attempted in the following paragraph.

(To be continued.)

## Original Articles.

### THE MENACE OF SYPHILIS OF TODAY TO THE FAMILY OF TOMORROW.

By J. HARPER BLAISDELL, M.D., BOSTON,

*Physician, Skin Department, Boston Dispensary; Dermatologist, Lynn Hospital; Assistant, Skin Department, Massachusetts General Hospital.*

[From the Records of the Skin Department of the Boston Dispensary.]

EVERY new case of syphilis confronts the community with three distinct problems menacing to its health and well-being. There is the menace of the source of the present infection,—in most instances uncontrolled,—the danger from which is shown by the presence of the new case. The case at hand becomes a menace in turn to the clean-living public in proportion to the extent of contact, the infectiousness of the lesions and the inadequacy of the treatment received. The third menace is the great probability of passing the disease to the present or future marital partner, and in time of blighting the coming generation.

Immoral sexual intercourse is the common source from which all cases of syphilis start. An absolute control at this point would mean the ultimate automatic control of the tragic by-products of the disease,—extra-genital, marital, and congenital syphilis. Prostitution in Boston is largely a matter of the individual. Organized vice in the form of tolerated, sharply bounded districts and protected houses does not exist. As a result, the majority of victims may as successfully look for the proverbial "needle in the haystack," as to find again their particular partner to the infection, who is still fitting without restraint through the countless accessories to vice in this city and its suburbs. Thus, under the present vice conditions in Boston, even the most elementary follow-up work to control foci of infections among the immoral can be done only under the most taxing handicaps.

The menace of the syphilitic to the clean living public is a very real one. In a previous article by the author<sup>1</sup> this particular phase of the problem in Boston has been dealt with in detail. The occupational and family life brings the syphilitic with active lesions in daily contact with many innocent people. That this peril is not one of theory alone is shown by the fact that the cities of New York, Toronto, and Boston are making examinations for contagious and infectious diseases among the restaurant workers. The syphilitic patients at our clinic make little effort to follow up even the most elementary treatment. Twenty-eight per cent. of our patients for one year never returned. The criticism that this condition is exaggerated or purely local is not sustained. In a statistical efficiency report of conditions in New York City, Barringer and

Platt<sup>2</sup> report that 29% of 116 patients in a city clinic came but once.

The history of preventive medicine can present to-day no greater tragedy of disease than the home invaded by syphilis. Infection from immoral relations is the result of a danger to which the individual exposes himself with open eyes. Extra-genital infection acquired in the way of ordinary living forms but a tiny percentage of the total number of cases. But hosts of innocent syphilitides of the home are compelled to bear the penalty for the wrong-doings of others in years of ill-health and by death.

A study of detailed cases of family syphilis brings a keener realization of the price that the community pays for the presence of syphilis in the home than any consideration of mass statistics. For this purpose thirty families were tabulated according to their medical and social histories as they appeared for treatment at the Skin Department of the Boston Dispensary. Members of this group are designated "syphilitic" or "healthy" only when the present condition has been unmistakably established. The other classifications are made, according to the best judgment of the writer, after careful consideration of the facts at hand. The cases in detail are as follows:

#### FAMILY 1.

*Husband.* Refused to come to the clinic for examination. Has always been healthy as far as his wife knows. (Probably syphilitic.)

*Wife.* Married three years and knew husband seven years previous to that. Showed late secondary syphilitic and complained of headaches. (Syphilitic.)

##### *Pregnancies.*

1. Miscarriage at 7 months. (Probably syphilitic.)
2. Miscarriage at 2 months. (Probably syphilitic.)
3. Miscarriage at 2 months. (Probably syphilitic.)

#### FAMILY 2.

*Husband.* Was given three injections of salvarsan at the Boston City Hospital three years ago but has not continued treatment for the past two years as he feels and considers himself well. (Syphilitic.)

*Wife.* Showed a late secondary syphilitic and complained of general pains. (Syphilitic.)

##### *Pregnancies.*

1. Boy, 7 years old, living and well. (Healthy.)
2. Girl, full-term, lived 40 minutes. (Probably syphilitic.)
3. Still-born. (Probably syphilitic.)

#### FAMILY 3.

*Husband.* Married at 22. Developed secondary syphilis a few months after marriage. Drank hard. Became feeble-minded and died at the Taunton Insane Hospital. (Syphilitic.)

*Wife.* Married at 18. Left husband ten times because of drunkenness and abuse and returned on his promises to reform. Came to the clinic with mucous patches, hoarseness and headaches. (Syphilitic.)

##### *Pregnancies.*

1. Miscarriage at 6 months. (Probably syphilitic.)
2. Induced miscarriage at 3 months.
3. Boy, died in 2 days. (Probably syphilitic.)
4. Miscarriage at 2 months. (Probably syphilitic.)

#### FAMILY 4.

*Husband.* Denied all venereal disease by history and by symptoms. Has a syphilitic aortitis of many years' duration. Is treating at the Peter Bent Brigham Hospital. Wassermann strongly positive. (Syphilitic.)

*Wife.* Married at 20. Denies all sexual relations previous to marriage. General health good except for chronic diarrhea of many years' duration. Wassermann strongly positive. (Syphilitic.)

##### *Pregnancies.*

1. Miscarriage at 8 months. (Probably syphilitic.)
2. Miscarriage at 5 months. (Probably syphilitic.)
3. Miscarriage at 2 months. (Probably syphilitic.)
4. Boy, 16 years old, living and well. Wassermann strongly positive. (Syphilitic.)
5. Miscarriage at 4 months. (Probably syphilitic.)
6. Miscarriage at 4 months. (Probably syphilitic.)
7. Girl, 12 years old. Has had "heart trouble" for years. Wassermann strongly positive. (Syphilitic.)

#### FAMILY 5.

*Husband.* Contracted syphilis two years before marriage. Did not have any comprehension of the seriousness of the disease and took treatment for only a little while. Feels perfectly well now and declines to take treatment under any circumstances. (Syphilitic.)

*Wife.* Married at 15 to her first husband, by whom she had five healthy children. Married second husband five years ago. Has had no symptoms of the disease. Wassermann strongly positive. (Syphilitic.)

##### *Pregnancies.*

6. Boy, 3 years old, congenital syphilitic. (Syphilitic.)
7. Girl. Died in 10 days. The child is said to have peeled and turned black. (Probably syphilitic.)

#### FAMILY 6.

*Husband.* Cured a "woman sickness" during his honeymoon. Is at present a soldier in the Italian army. (Probably syphilitic.)

*Wife.* Complained of general malaise and vague pains. Wassermann positive. (Syphilitic.)

##### *Pregnancies.*

- 1-7. Miscarriages. (Probably syphilitic.)
8. Girl, a congenital syphilitic, that died in two days. (Syphilitic.)

#### FAMILY 7.

*Husband.* Not under any treatment and nothing definite known about his condition. (Probably syphilitic.)

*Wife.* Has suffered with interstitial keratitis and severe headaches. (Syphilitic.)

*Pregnancies.*

1. Miscarriage at 7 months. (Probably syphilitic.)
2. Miscarriage at 7 months. (Probably syphilitic.)
3. Miscarriage at 7 months. (Probably syphilitic.)
4. Boy, 5 months old, congenital syphilitic. (Syphilitic.)

## FAMILY 8.

*Husband.* (First.) Nothing known about his health or his present whereabouts. (Probably syphilitic.)

*Husband.* (Second.) Old syphilitic case, now starting locomotor ataxia. Wassermann strongly positive. (Syphilitic.)

*Wife.* Married first husband at 17. Divorced him three years later for unfaithfulness. Married second husband at 25. No pregnancies by second husband. Wassermann strongly positive. (Syphilitic.)

*Pregnancies.*

1. Miscarriage at 3 months. (Probably syphilitic.)

## FAMILY 9.

*Husband.* Was always sickly, had a cough, lost his voice, and finally died of what was supposed to be tuberculosis. (Probably syphilitic.)

*Wife.* Has always been well except for gummata of the legs. (Syphilitic.)

*Pregnancies.*

1. Miscarriage at 8 months. (Probably syphilitic.)
2. Miscarriage at 6 months. (Probably syphilitic.)
3. Miscarriage at 6 months. (Probably syphilitic.)

## FAMILY 10.

*Husband.* Had intercourse with many women during his early married life. Took spasmodic treatment for syphilis from various doctors. Died suddenly of "heart trouble" two years ago. (Syphilitic.)

*Wife.* Has had poor health and pains in the legs and the chest for years. Wassermann strongly positive. (Syphilitic.)

*Pregnancies.*

1. Still-born. (Unclassed.)
2. Boy, 14 years old, living and well. Wassermann negative. (Unclassed.)
3. Boy, 12 years old, that has "fits." Wassermann strongly positive. (Syphilitic.)
4. Boy, 10 years old, that has always been sickly. Wassermann strongly positive. (Syphilitic.)

## FAMILY 11.

*Husband.* Denies all venereal disease and feels perfectly well. Wassermann moderately positive. (Syphilitic.)

*Wife.* Complaints of headache, indigestion and vague symptoms. Health had always been excellent up to the beginning of the first pregnancy. Is now two months pregnant. Wassermann strongly positive. (Syphilitic.)

*Pregnancies.*

1. Boy, 16 months old, strong and healthy in every way. Wassermann moderately positive. (Syphilitic.)

## FAMILY 12.

*Husband.* Began to have immoral relations with women shortly after marriage. Hard drinker and has been committed to state institutions four times. Is not living with wife at present. (Probably syphilitic.)

*Wife.* Married at 18. General health has always been good. Wassermann moderately positive. (Syphilitic.)

*Pregnancies.*

1. Girl, died at four months of unknown trouble. (Unclassed.)
2. Miscarriage at 4 months. (Probably syphilitic.)
3. Miscarriage at 6 months. (Probably syphilitic.)
4. Miscarriage at 4 months. (Probably syphilitic.)
5. Boy, 10 years old, that has a syphilitic hip trouble. (Syphilitic.)
6. Girl, 7 years old, living and well. (Unclassed.)
7. Girl, 4 years old, living and well. (Unclassed.)

## FAMILY 13.

*Husband.* Denies all venereal disease and health has always been excellent. Wassermann strongly positive. (Syphilitic.)

*Wife.* Married at 15 in Syria. Health has always been good. Wassermann moderately positive. (Syphilitic.)

*Pregnancies.*

1. Girl, 24 years old, living and well. (Unclassed.)
2. Miscarriage at 4 months. (Unclassed.)
3. Girl, 20 years old, living and well. Wassermann negative. (Unclassed.)
4. Boy, 18 years old, that is very feeble-minded. (Probably syphilitic.)
5. Miscarriage at 3 months. (Probably syphilitic.)
6. Boy. Became "crippled" so that he was never able to walk, and died at 9 years of an unknown trouble. (Probably syphilitic.)
7. Miscarriage at 2 months. (Probably syphilitic.)
8. Girl. Became "crippled" at 4 months in the same way as did Child 6 and died at 5 years. (Probably syphilitic.)
9. Boy. Became "crippled" at 4 months as did the other children and died at 2 years of congenital syphilis in the Children's Ward of the Boston Dispensary. (Syphilitic.)

## FAMILY 14.

*Husband.* Contracted syphilis a short time before marriage. Has had irregular treatment for several years. (Syphilitic.)

*Wife.* Married at 17. Health has always been excellent. Wassermann moderately positive. (Syphilitic.)

*Pregnancies.*

1. Girl, 18 years old, that is a congenital syphilitic. (Syphilitic.)
2. Boy, 16 years old, living and well. (Unclassed.)
3. Boy, lived only 4 hours. (Probably syphilitic.)
- 4-10. Woman claimed to have caused 7 miscarriages in succession by introducing a catheter

dipped in vaseline into the uterus when she was about three months pregnant.

11. Girl, 4 years old, congenital syphilitic. (Syphilitic.)

#### FAMILY 15.

*Husband.* Contracted syphilis before marriage. Has been insane for 14 years and is at present confined in one of the State Hospitals for the Insane. (Syphilitic.)

*Wife.* Married at 20. Husband was "queer" at the time she married him. Has suffered from severe headaches for years. Wassermann strongly positive. (Syphilitic.)

#### Pregnancies.

1. Still-born. (Probably syphilitic.)
2. Miscarriage at 2 months. (Probably syphilitic.)
3. Miscarriage at 5 months. (Probably syphilitic.)
4. Boy, died at 8 months of "brain trouble." (Probably syphilitic.)

#### FAMILY 16.

*Husband.* Contracted syphilis about 9 years ago. Took treatment for only a few months. (Syphilitic.)

*Wife.* Healthy in every way according to the husband, who declines to have her come to the hospital for observation. (Probably syphilitic.)

#### Pregnancies.

1. Boy, 18 years old, living and well. (Healthy.)
2. Girl, 16 years old, living and well. (Healthy.)
3. Girl, 11 years old, living and well. (Healthy.)
4. Miscarriage at 4 months. (Probably syphilitic.)

#### FAMILY 17.

*Husband.* Wife states that he is a "cheap sport." Since marriage continues immoral relations with women, and in one instance was the father of an illegitimate child. (Probably syphilitic.)

*Wife.* Married at 19. Husband deserted her about a year ago. Has always been the sole means of support for the family. Is now working in a candy factory and is applying for a divorce. (Syphilitic.)

#### Pregnancies.

1. Miscarriage at 4 months. (Probably syphilitic.)
2. Miscarriage at 7 months. (Probably syphilitic.)
3. Miscarriage at 7 months. (Probably syphilitic.)

#### FAMILY 18.

*Husband.* Came to the clinic 6 years ago and was treated for two months only. No treatment since. (Syphilitic.)

*Wife.* Complains of headaches and has gummata on the legs. Has been taking occasional treatment for 5 years. (Syphilitic.)

#### Pregnancies.

1. Boy, 9 years old, living and well. (Healthy.)
2. Boy, 6 years old, that has been treated for congenital syphilis since birth. (Syphilitic.)

#### FAMILY 19.

*Husband.* Characterized by wife as a "cheap sport" and a hard drinker. Had immoral relations with other women beginning three weeks after marriage. Deserted wife 4 years ago. (Healthy.)

*Wife.* Married at 21. Knew husband only a few weeks before marriage. Two years following separation from her husband she met a musician, whose special attraction was a touring car. He has a wife and five children. Through him this woman contracted syphilis and became pregnant. With the help of the Children's Aid Society the case was settled for \$500 and a monthly payment of \$10 to the grandmother for taking care of the child. Woman came to the clinic with a late rash and lesions on the palms. Wassermann strongly positive. (Syphilitic.)

#### Pregnancies.

1. Girl (by husband), 6 years old, living and well. (Healthy.)
2. Boy (by musician), 9 months old, with syphilitic periostitis and snuffles. (Syphilitic.)

#### FAMILY 20.

*Husband.* Nothing definite known about his habits. Died of pneumonia 4 months after marriage. (Syphilitic.)

*Wife.* Pretty but mentally defective girl. Married in January, 1913, at 18. Developed syphilis and became pregnant in February. Husband died in April. Congenital syphilitic child born in November. Since that time the baby has received institutional care in various places and the mother has worked as a waitress in many restaurants, including eight months at a Wellesley College dining hall. In spite of 8 salvarsans and much mercury at another hospital, the girl appeared in the clinic for the first time with mucous patches, split papules, and very extensive condylomata. The menace that she was to others was particularly impressed upon her at that visit. One week later the patient returned and stated in an embarrassed way that the night following her visit to the clinic she had yielded to the persuasion of a persistent suitor and was married to him by a justice of the peace. Learning of his wife's condition the bridegroom left his wife 10 days after marriage and is now suing for divorce. It is not known whether he became infected. The girl is now working as a waitress, and, according to her own story, is leading the life of a common prostitute. She is also pregnant by a party unknown to her. (Syphilitic.)

#### Pregnancies.

1. Boy, 19 months old, congenital syphilitic. (Syphilitic.)

#### FAMILY 21.

*Husband.* Has always been in good health and refused to be examined. (Probably syphilitic.)

*Wife.* Has been in poor health for years. Wassermann strongly positive. (Syphilitic.)

#### Pregnancies.

1. Boy, 9 years old, living and well. (Healthy.)
2. Girl, died at 4 years of diphtheria.
3. Still-born. (Probably syphilitic.)
4. Still-born. (Probably syphilitic.)
5. Still-born. (Probably syphilitic.)
6. Still-born. (Probably syphilitic.)

#### FAMILY 22.

*Husband.* Runaway marriage at the age of 21. Never lived with his wife and the marriage was never known. (Healthy.)

*Wife.* Married at 16. General health has always been excellent. Came to the clinic with a late syphilitic eruption. Has had one "friend" for the

past 14 years by whom she has been pregnant twice. (Syphilitic.)

*Pregnancies.*

1. Miscarriage at 5 months. (Probably syphilitic.)
2. Miscarriage at 3 months. (Probably syphilitic.)

FAMILY 23.

*Husband.* Denies all venereal disease. Trouble started one year ago with girdle pains and dizziness when walking. Now has a well advanced case of locomotor ataxia. Wassermann strongly positive. (Syphilitic.)

*Wife.* Denies all exposure other than husband. Has always been in good health. Wassermann strongly positive. (Syphilitic.)

*Pregnancies.*

1. Girl, 3 years old, living and well. (Probably syphilitic.)
- 2 and 3. Twin boy and girl, 6 months old, living and well. (Probably syphilitic.)

FAMILY 24.

*Husband.* Is a member of a fire department. Has always been a periodic hard drinker and has had constant immoral relations with women since marriage as well as before. Contracted syphilis from a prostitute while on a drunk two years ago. His wife was pregnant with the third child at the time. (Syphilitic.)

*Wife.* Contracted syphilis from her husband shortly after his exposure. (Syphilitic.)

*Pregnancies.*

1. Boy, 6 years old, living and well. (Healthy.)
2. Girl, 4 years old, living and well. (Healthy.)
3. Girl, 6 months old, congenital syphilitic. (Syphilitic.)

FAMILY 25.

*Husband.* Previous history and present condition unknown. (Probably syphilitic.)

*Wife.* Contracted syphilis from a friend three years previous to her marriage. Treated with a private doctor for two years and was pronounced cured. Married in August, 1914. Wassermann moderately positive. (Syphilitic.)

*Pregnancies.*

1. Boy, died in 2 months of congenital syphilis. (Syphilitic.)

FAMILY 26.

*Husband.* Has had two attacks of gonorrhea and contracted syphilis two years before marriage. Received a month's treatment for syphilis from a private doctor. Has had immoral relations with four or five girls since marriage. (Syphilitic.)

*Wife.* Felt perfectly well and could not be induced to come to the clinic for examination. Husband states that she has occasional immoral relations with "friends." (Probably syphilitic.)

*Pregnancies.*

1. Miscarriage at 7 months. (Probably syphilitic.)

FAMILY 27.

*Husband.* Contracted syphilis in 1910. Has taken no treatment and leads a generally dissipated life. (Syphilitic.)

*Wife.* Married at 19 and is now 38 years old. Has been pregnant 15 times, 12 times before her husband's infection and 3 times since. Of the first 12 children 5 are living and well and 7 died of chil-

dren's diseases. This woman has had very fair health for the past twenty years. The syphilitic children have been under institutional care since birth. At the time of writing she is 5 months along in her 16th pregnancy. Wassermann moderately positive. (Syphilitic.)

*Pregnancies.*

13. Boy, 3 years old, congenital syphilitic. (Syphilitic.)
14. Girl, 2 years old, congenital syphilitic. (Syphilitic.)
15. Girl, 1 year old, congenital syphilitic. (Syphilitic.)

FAMILY 28.

*Husband.* Previous history and present condition unknown. Is too busy with his daily work to come to the clinic. (Probably syphilitic.)

*Wife.* General health has been good. First two children were born in Russia. Wassermann weakly positive. (Syphilitic.)

*Pregnancies.*

1. Girl, 16 years old, living and well. (Healthy.)
2. Boy, died at 10 months of smallpox.
3. Miscarriage at 3 months. (Probably syphilitic.)
4. Miscarriage at 3 months. (Probably syphilitic.)
5. Girl, died at 5 years of appendicitis. (Probably syphilitic.)
6. Girl, 5 years old, congenital syphilitic. (Syphilitic.)

FAMILY 29.

*Husband.* General health poor. Contracted syphilis shortly before marriage and is taking treatment from private doctors. (Syphilitic.)

*Wife.* Had three healthy children by her first husband. Contracted syphilis from her second husband 25 years ago. General health good. On coming to the clinic she showed an active palmar syphilitic. (Syphilitic.)

*Pregnancies.*

4. Still-born. (Probably syphilitic.)
5. Still-born. (Probably syphilitic.)
6. Boy, 21 years old. Lost sight of one eye at 4 weeks and the sight of the other at 7 years for unknown reasons. Is not normal mentally. (Probably syphilitic.)

FAMILY 30.

*Husband.* Contracted syphilis from a married friend during his wife's pregnancy. Wassermann strongly positive. (Syphilitic.)

*Wife.* Came to the clinic with active secondary lesions. Wassermann strongly positive. (Syphilitic.)

*Pregnancies.*

1. Boy, 3 months old, congenital syphilitic. (Syphilitic.)

A statistical summary of the ravages of syphilis in these thirty families is as follows:

HUSBANDS.	
Syphilitic .....	19
Probably syphilitic .....	10
Healthy .....	3

(Syphilitic).....	53
Miscarriages.	
(Other causes).....	8
Intercurrent diseases with syphilis.....	6
Other diseases.....	9
Unclassed.....	3

Total.....79

Total pregnancies.....132

**Husbands.** Less than 10% escaped the infection. Four died with syphilis a contributing factor. Two suffered with insanity. Twelve out of a possible twenty-five are not taking any treatment.

**Wives.** Twenty-eight out of thirty of the women were infected, and the remaining two probably had the disease. The women were usually the first members of the family groups to come to the clinic and number under treatment is relatively large when compared with the number of the men.

**Pregnancies.** There were 132 definite pregnancies in these thirty families. These resulted in only 23 healthy children, the large majority of whom were born before infection entered the family. Of the 53 living children syphilis claims at least 24 or 45%. In the cases of the 79 deaths syphilis may be credited as the probable causative factor in at least 59 or 74%. Totaling, syphilis scores in 83 out of 132 pregnancies, or 62%.

The early syphilis of to-day can well be depended upon to furnish the family syphilis of tomorrow. Syphilis is usually acquired by the unmarried of both sexes in early adult life. Lulled to a false security by the lack of symptoms after a short course of treatment the patients marry. The marital partners may appear

in the clinic with the early symptoms of syphilis and the originators reappear with the late lesions. The truth of this generality is shown by a tabulation of the type, age, and marital status at the time of entrance of 500 consecutive cases of adult syphilis in this clinic.

## SINGLE MEN.

Late	0	1	7	8	26	42	.084
Total	0	14	24	22	38	98	
Total %	.000	.028	.048	.044	.076	.196	.196

## MARRIED WOMEN.

Age.	—20	21-25	26-30	31-40	41+	T.	T. %
Early	3	3	0	6	2	14	.028
Secondary	8	18	12	22	7	67	.134
Late	0	1	2	21	26	50	.100
Total	11	22	14	49	35	131	
Total %	.022	.044	.028	.098	.070	.262	.262

**Single Men.** (236 Cases.) The single men comprised over 47% of the entire number of cases. Two hundred and twelve had early or secondary syphilis, and 172 (72%) contracted the disease before their thirtieth year. Considering that a large proportion of these men will marry and that on an average 70% of them make less than five visits to the clinic, the tremendous danger to their future homes can be realized.

**Single Women.** (35 Cases.) Where does the clinic's quota of single women, proportionate to the number of single men, go for treatment? With few exceptions the 236 single men probably represent as many different women who have been active foci. Yet the group of single women coming to the clinic is nearly 85% less than the group of single men. Statements from many doctors are all in agreement that the number of single women among their private patients is proportionately small. The bringing under medical supervision of the relatively large number of single women, now apparently under no control, would go a long way toward removing

active foci of infection and minimizing the danger to their future husbands and children. As with the single men, syphilis was acquired at an early age, 29 out of 35 contracting it under 25 years of age.

**Married Men.** (98 Cases.) Among the married the tide turns toward the later stages of the disease. Sixty out of 98 cases came to the clinic after their thirtieth year and nearly half the cases presented late symptoms.

**Married Women.** (131 Cases.) In contrast to the single women, the number of married women is considerably larger than the number of married men. It is in this group of "women of the home" that the members missing from the group of "women of the street" appear with the later lesions of the disease. Only 14 of the 131 married women came to the clinic with lesions of less than three months' duration. Fifty or 38% of the number had late or gummatous lesions.

#### SUMMARY.

1. The menace of syphilis in the home is one of the greatest problems of preventive medicine.
2. In thirty families, 59 out of 62 parents were probably infected.
3. Of 132 possible children, only 23, most of whom were born before their parents' infection, were healthy.
4. Of the remaining 109, syphilis claims through miscarriage, later death, or congenital disease at least 83 pregnancies.
5. Syphilis will appear in the home of tomorrow in proportion to the inadequacy of treatment among the "men and women of the street" of today.

## VAGINAL HYSTERECTOMY FOR PROLAPDENTIA, WITH A REPORT OF FIFTY CASES.\*

By P. E. TRUESDALE, M.D., FALL RIVER, MASS.

THE surgical problem which deals with complete prolapse of the uterus is in principle similar to that applied to the cure of hernia elsewhere. The operation involves the excision of a large pendulous sac with the reduction and retention or removal of its contained organs. The over-stretched bladder and rectum are detached from the sac and allowed to contract. The bladder must be elevated and supported upon a shelf erected by an appropriate use of the pelvic ligaments. The importance of creating a deflecting plane as an effective resistance to intra-abdominal pressure is paramount. Goffe<sup>1</sup> quotes Sturmdorf in his own elaboration of this principle.

\* Read before the New Hampshire Surgical Club, April 11, 1916.

Vaginal hysterectomy is one of the very useful operations employed in the execution of these measures. Its application is limited to a class of cases in which conservation of the uterus may be disregarded. The wisdom of its choice, however, in most cases, has been a subject of controversy. Many of the continental authors favor the Wertheim-Shauta operation which preserves the uterus, while in America a fair division of opinion is maintained toward the Watkins-Wertheim anterior transposition operation, vaginal hysterectomy, and some form of suspension or fixation of the uterus. Goffe,<sup>2</sup> and C. H. Mayo,<sup>3</sup> among others, advocate vaginal hysterectomy in a group of patients past forty years of age, manifesting prolapse of the complete type.

In general, the details of technic will vary to meet the requirements in each case. The uterus may be found in a state of sub-involution or atrophy, but the one constant and often startling revelation is the unusual length of the cervix, often exceeding that of the body by several centimeters.

The weak point may be in front of the uterus in the region of the bladder or it may be the uterosacral ligaments and perineum, allowing the descent of the uterus and rectum. In patients over fifty years of age the tissues are often found

PLATE I.—Prolapsed of the complete type. Reproduced from Case 44. Figs. 2 and 3 show the first incision overlying the cervix. The bladder is exposed anteriorly and the rectum posteriorly.

to have undergone degeneration, are friable, and thus allow the sutures to cut through. The obvious result is a weak, imperfect union of the broad ligament stumps, or no union at all. A solid pelvic floor is very essential to success but it will not support the vaginal walls without a reasonable support above. An occasional failure in my series of cases was undoubtedly due to a separation of the broad ligament line of union. To make better provision against such faulty union of the broad ligament stumps, I have modified the operation to include a strip of uterine muscle on either side, making an apposition of the broad ligaments with a strip of uterine muscle to form a central body of support. This method in many cases will serve to fortify a weak step in the operation as usually done. The procedure differs from the operation described by Watkins, inasmuch as the entire cavity and elongated cervix are removed. In other respects the technic does not differ essen-

tially from that commonly used and may be described as follows:

The cervix is first grasped with a volsellum forceps. While held in position an incision is made encircling the cervix immediately below the bladder line. By sponge dissection the bladder is separated from the elongated cervix up to the peritoneal fold, which is deflected from the uterine body to the bladder. This is opened while the bladder is supported upon the long flat blade of a retractor. The mucous membrane in the lateral and posterior sulcus of the vagina is also separated by sponge dissection. The uterine artery on either side is tied and cut. The fundus uteri is then delivered through the peritoneal opening in front and the central portion of the uterine body with the entire cervix is removed after the manner illustrated in Plate III. Apposition by interrupted catgut suture is then made of the uterine muscle stumps of the broad ligaments. Upon the anterior surface of this central body is now sutured the dependent portion of the bladder, two or three catgut sutures being used for this purpose. The remaining distance of this central

body is sutured by interrupted catgut ligatures to the anterior vaginal walls, or the central body of the uterine muscle, above described, may be turned forward under the bladder after the manner described by Watkins. No drainage is used; a perineorrhaphy completes the operation. A self-retaining catheter is then inserted and left in place for forty-eight hours. This allows the bladder wall to contract and removes from the suture line the weight of accumulating urine.

Analysis of the fifty cases here recorded, in which vaginal hysterectomy was done for procidentia, shows that the ages of the patients at the time of operation averaged fifty years. The average duration of symptoms was five years. Ten patients had each given birth to ten children or more; nineteen had each borne between five and ten children; seventeen had each less than five children; and four were nulliparae. Sixteen patients reported that their labors had been normal. Twenty-four had been delivered

by the use of instruments and six had been attended in labor by a mid-wife on one or more occasions. In forty-two cases the procidentia was complete; in eight the descent was incomplete, the vaginal portion of the cervix resting on the anterior margin of the perineum.

In the investigation of the present condition of these patients, thirty-eight were examined by Dr. George W. Blood, Dr. Ralph W. French, and myself. Eight reported by letter and four could not be traced. The following evidence was obtained: Thirty were found to have secured good anatomical results and were free from pelvic discomforts; seven reported well but were not examined; six complained of local discomforts and were found to have some degree of cystocele or rectocele. In none of these six cases, however, was there a descent of the vaginal walls below the pudendal fissure. There were three failures and four patients could not be traced. We have, therefore, direct or indirect

FIGURE 11.—Separation of the bladder from the cervix up to the peritoneal fold. The sponge-covered finger is here used for dissection.

PLATE III.—A rubber covered clamp is applied to the broad ligament about 1 cm. from the uterus. Dotted line shows the depth of the vertical incision in the muscle of the uterine body. Note the greatly elongated cervix.

FIGURE 14.—Fig. 13. Uterine muscle brought together forming a central body for resistance to intra-abdominal pressure and a support to the bladder. Dependent portion of the bladder is sutured to the central line of muscle structure. Fig. 14. A lateral view shows the relation of the uterine muscle and bladder when the operation is completed.

PLATE V.—Transposition of the uterine muscle body between the bladder and anterior vaginal wall.

evidence of complete success in 74%, partial success in 12%, and failure in 6%.

Although sufficient time has not elapsed for final opinion, the operation now done, as illustrated in Plates III, and V, has been employed with uniform success since January, 1915.

## THE GENERAL PRACTITIONER'S APOLOGIA PRO VITA SUA.

By ANDREW F. DOWNING, M.D., CAMBRIDGE, MASS.

A LACK of unity among its members, and an excess of organization which threatens to become pathological are the ills that disturb to-day the peace and harmony of the medical profession. The general practitioner, beloved of other days, finds himself obliged to mitigate the presumption of his claim to medical knowledge by a proper sense of humility in the presence of the modern specialist. At the big medical meetings, he is confronted with a confusing list of section and sub-section meetings, and when, like a man without a country, he wanders aimlessly into a conference in the hope of gleaning some knowledge, he is too often obliged to listen to a dissertation on his own shortcomings. For him there seems to be no place. He appears to

be only a convenient *causa mortis* of the patients of specialism, merely an ever ready excuse for the advertising of that new human paradox of medical origin, the ethical quack. Occasionally he is praised for his heroism, seldom for his knowledge; but he has at last come to recognize that this, too, is the same brand of altruistic hypoerisy that vice so often exhibits when she generously pays public tribute to virtue.

There is a fable told of the man who invited the lion to be his guest and received him with princely hospitality. The lion was shown many things to admire, countless specimens of sculpture and painting, nearly all of which represented the lion in combat with man and in which the man was always victorious and the lion always overcome. After he had gone over the mansion, his host asked him what he thought of the splendors it contained. In reply he did full justice to the riches of the owner and the skill of the decorators, but he added, "Lions would have fared better had lions been the artists."

A propaganda, characterized by cowardly and insidious attack, that has for its purpose the commercial elevation of the specialist or surgeon at the expense of the good name of the general practitioner, cannot be allowed to flourish. The time has come for the lion to be the artist. The specialist has boldly thrown down the gauntlet to the general man, and the latter must pick it up.

The primary purpose of our medical organization is to further the usefulness and dignity of the profession. No reputable man is debarred, even though he be a general practitioner. Organization is the instrument of reform, the method of intelligent coöperation for the greatest good; while the lack

of organization means inefficiency, waste of individual effort, and absence of coöperation for the good of all. The result of the latter condition is victory for the enemies of reform and the triumph of a machine.

At the beginning I stated that we were menaced by excess of organization at the price of the unity of our members. Divisions into the specialties, and subdivisions into the branches of the specialties, have resulted in a chaotic mass of antagonistic smaller bodies that seem to have nothing in common but contempt for the man in the ranks. Now excess of organization means rigidity, uniformity, and mechanical perfection, that ultimately, unless properly safeguarded, results also in the triumph of a machine. Therefore, either from lack of organization or excess of it you face the machine, which may be a weapon of corruption, an enemy of reform, a means of subverting the common welfare to unintelligent or selfish ends. And while it would be perhaps unfair to say that in the medical world a corrupt machine has arisen which can be accused of unintelligent measures, nevertheless, it is true that we are confronted with a pseudo-aristocracy whose besetting sin is a selfishness that forgets the old-fashioned courtesy "which makes a man shrink from wounding the feelings of a brother practitioner."

The general man is aware of his many imperfections. Too often, perhaps, his increasing income results in complacency and inertia, until in his lotus land of secure mediocrity, he dreams only of dollars and eagles. And yet has he not like companions among the specialists? However, mental apathy is not the rule. The general practitioner rightfully feels that any successful and honest attempt to uplift the rank and file must be accompanied and even preceded by a similar movement to rid the field of specialism of its many mushroom growths.

The solution of the problem does not consist in giving to the public the untruthful impression that the general practitioner represents only mediocrity or inefficiency, and that the magic word "specialist" always connotes education, training, experience, competency, skill, culture, and intellectuality. The true specialist had his origin in the halls of learning in the days before commercialism began to exercise its evil influence. He did not, however, stand at the gates of his citadel and, beating back commercialism, mediocrity, and inefficiency, open them wide only for the man of merit. He did not protect his stronghold by driving out those who proved unworthy of the privilege of service either through incompetency or misconduct. Gradually he allowed his place to be usurped by many who were unfit, until his house was no longer the exclusive abiding place of rare skill and profound knowledge. The new specialism begot too many men whose ignorance and effrontery, by causing them to leap where

angels fear to tread, have done much harm to those efficient specialists for whom the general practitioner has the highest regard.

It is no exaggeration to say that never has the general man entered upon his work so well equipped as at the present time. It would be an exaggeration to say the same of the specialist, who in broad vision, skill, training, experience, culture, and the arts of thinking and of observation is seldom the superior of the general man, whom he dares to treat with contemptuous patronage. The man in the ranks would be cringing if he did not rise to protest against this brazen hostility that would be much more seriously offensive to good manners, were it not rendered so amusingly ridiculous by the sublime mediocrity of this era of rampant specialism. The general practitioner has always been patient with the specialist, because courtesy and common decency have forbidden him to "draw his frailties from their dread abode." If he is now in many quarters proving to be the David to whom the Kingdom of Specialism is falling, it ill becomes the specialist to look upon him as a king of shreds and patches. The general practitioner who, in his hospital days, has rubbed elbows with him who is now practising a specialty with a slovenliness that is the handmaid of ignorance, is not likely to be awed by the fact that such a man is the "rage" among a select group of society leaders. Moreover, he refuses to pay homage to that other anomaly of specialism who, after a course of beer-sipping and wine-tasting in Heidelberg or Vienna, returns to his friends "amid the crash of brass and the beat of drum," bloated with insolent conceit, and mottled with poisonous contempt for the lowly practitioner. In short, your general man has concluded that if the specialist would only spend his days and nights striving to reach a height equal in distance to the depths into which he would plunge him, specialism by extending its horizon would at last find the "blessedness of being little" and cease to be a danger to humanity.

"So waxes fierce the strife between these god-like men." "Shun the general man," shouts the specialist to the public, "for only with us lies the knowledge that leads to bodily salvation." "Beware the specialist," retorts the general man, "and the dead and maimed will be fewer in the land." Which is right? Neither. Somewhere between the bold assertion of omnipotence of the one, and the amusing assumption of omniscience of the other lies the truth. In the political and industrial worlds there are arising many problems the solution of which is taxing to the uttermost the intellects of our greatest leaders. Preparedness is the burning question of the hour. We, too, must be prepared, for the medical world has its own problems the solving of which will "stretch to aching the *pia mater*" of her combined leadership. The problem of the general practitioner is a

social one, inseparable from many others, which no single expert is wise enough to solve. It does not suffice to tell him that this refinement of organization is necessary for the good of all, while he feels that he is held in dishonor by the small group of individuals who reap the benefit. Many a strike has occurred in an industry which was effectively organized to increase material output, but which crushed the human nature of the workers until they were roused to rebellion. The general practitioners of today, with their excellent training, and exceptional opportunities for acquiring new medical knowledge, are becoming more and more conscious of their rights and dignity as members of the medical profession; and they resent the arrogance and truculence of petty men of inferior minds upon whom accident has too often bestowed the high places. They demand respect, not as a favor, but as a just right. They will not accept the dictum that the only escape from the ranks is death, but insist that he who possesses the skill, the knowledge, and the brains to enter some special field of work be not blocked by special privilege and outspoken contempt.

Herein lies the failure of specialism and herein lies an opportunity for our medical organization. We lack a department of administration that shall set and maintain standards of efficiency for all. To say that a man is qualified to do special work because of a few months' training in a hospital is ridiculous. The inefficient interne, without capacity for development, begins his professional life after graduation, the equal of the most proficient, and he may continue his career in the same condition with impunity. Abdominal surgery is being done by men notoriously incompetent, who graduated from hospitals of reputation. Yet there is no supervising authority in our medical organization to stay their hand. A surgical training as an interne, regardless of one's ability or qualifications, seems to be the only recognized ticket of admission to the domain of surgery; and the same is true of other special fields. And he who enters the inferno of general practice must, according to present-day standards, face the sentence that Dante inscribed over the gates of hell: "All hope abandon ye who enter here." Worse even than that of Tantalus is his fate, for after having entered the gates, he must look back and see his brothers, the specialists, like demagogues, haranguing the public on his ignorance and warning them off by pointing to the inscription over the abode he has just entered.

In the past decade we have undertaken to educate the public in many things medical. Political leaders have done the same in matters pertaining to government. The initiative and referendum, the recall of judges and executives, the minimum wage, the creation of boards of labor and industry, the passage of workmen's compensation acts, old-age pensions, the call

for constitutional conventions,—all are evidences of the people's demand for social justice. There are many who feel that a closer adherence to the landmarks of our fathers and a more honest administration of justice, according to the laws they framed, would have avoided all this clamor for social equality. The people, however, once aroused, are insistent on their demands and political parties are wise enough to heed their cry, and anticipate their uncanny intelligence in whatever concerns their welfare. Let the medical profession beware, lest their free public lectures prove to be dragons' teeth from which armed giants shall spring. Let us, too, awake from our apathy and anticipate the demands of the people by showing a willingness to grapple with a few of the problems that concern the public, as well as the good name and progressiveness of our profession.

First among these serious problems is one that we have grossly neglected. Our hospitals, public and private, are too far removed from the wise supervision of our organization. A supervising power, wise as the serpent and gentle as the dove, can never be obnoxious. Hospitals derive their right to existence from the people, and, therefore, it is our duty, through impartial and honest inspection, to protect the people by seeing that a proper standard of efficiency is maintained. The private or open hospital is where such inspection is most needed. Primarily a commercial venture, it offers to the inefficient an opportunity to hide a slovenliness of work that makes it impossible, as Osler says, "for that kind old friend Dame Nature to cover their mistakes." This is the curse of all hospitals with open staffs. It is true that the patients who enter such institutions are usually the well-to-do, whose knowledge of the world ought to enable them to choose men of skill. But the old saying "where ignorance is bliss 'tis folly to be wise" becomes a fallacy here, and a word in time may save more than nine lives. With no supervision, therefore, poor work is unconsciously encouraged and ideals are allowed to become forgotten things.

Here it is that many an unskilled general man falls into the slough of medical despond, where "besieged with sable-coloured melancholy" he grieves that a good surgeon was spoiled in his making. He deceives himself that surgery is just cutting, and its fatalities, like taxes, inevitable. His brain, slumbering unto death, is overcome by intellectual marasmus and ethical anemia; his conscience suffers a kypnosis; at last all "sense is apoplex'd"; and he who goes to bed at night a physician, awakes in the morning a surgeon, determined to have his share in the graft of human life. Think not that this is facetious exaggeration. The value of human life dwarfs all exaggeration and transcends the most extravagant hyperbole. The general man is not proud of these metamorphoses in his ranks, but he blames the conditions

that make them possible. As long as the Simon Pures are allowed to set the bad example of inefficiency by selling to the people surgical green goods, we must pay the shameful toll levied by those who will not hesitate to counterfeit these green goods. Happily there are many in the ranks of the general practitioners of whose work in surgery and other specialties their colleagues are justly proud. Particularly is this true away from the larger centres where the divine right of specialism is not recognized and medical feudalism is unknown.

In the case of our larger public or semi-public hospitals, the question of having an open staff should never be considered. Fortunately, in this community, such institutions are jealously guarded. Built as a rule by the people, and for the people, many of whom are poor and unfortunate, these monuments erected for the care of suffering humanity should be held sacred. The great body of solid general practitioners are strong supporters of the closed staff, because they feel a personal interest in the patient, that almost forgotten and yet most important figure in all our medical controversies. The general man realizes that by making the entrance gate to staff preferment in these hospitals narrow and difficult to pass, the exit for his patient to health and happiness will be broad and spacious. Therefore, a kindly supervision by our organization will harm no institution that it tries to help.

Some day the idea of publishing end-results will be hailed as a rock of safety for the people, and a God-send to the medical profession. Unless we take the initiative, the people, through their representatives, will compel hospitals from time to time to make a public statement of their standing, especially as regards mortality. The state throws its protection around our banks that the funds of the people may be properly secured, and even of their own accord, at various times, our banks issue a statement to the public press as proof that they are solvent. The funds entrusted to hospitals are human lives, and surely the public ought to know something about their disposal. Today, lawmakers are heeding the demand that our public servants be held up to a high standard of efficiency by expert investigation at stated intervals. This is because the people are insisting that in return for their money they receive efficient service. They have also a right to ask that in their hospitals, both public and private, their lives be protected by every possible safeguard. The American College of Surgeons is to be congratulated for its attempt to rouse the interest of the people in this respect, but, being an organization of surgical aristocrats, it is open to the charge of narrowness. If hospital reform is to become a serious business, the American Medical Association cannot sidestep the responsibility or look upon it as a

simple contract to be sublet to a group of subordinates, or to an independent corporation.

The federalization of our state boards of examination for admission to practice is another question that only persistent effort will solve. What matters it if defeat after defeat be our lot if undaunted we return to the fight? In numbers there is strength, but we seem not to have learned it. Witness our weak efforts in this state in favor of a clean milk bill, and in opposition to a bill to legalize the business of an herb doctor. What we sadly need is a leadership that will mould this great medical organization of ours into a powerful engine of aggressive efficiency in legislation and in medical progress, that will protect the lives and the health of our people and bring to us their undying gratitude and unsolicited support. To conceive our medical association as such an instrument challenges the imagination and provides for envy, hatred, and malice among our members a speedy and happy death. History shows that the course of events in human affairs under a hand-picked leadership, like labor, consists of three stages: feigned enthusiasm, apathy, and rebellion. We are still in the long second stage. Legislative hearings on medical matters attract but few of the many, who by convincing and dignified argument, might save our cause from defeat and give much needed strength to our whole body. Only by an organization, working in a spirit of harmony and brotherhood, can an antiquated system that controls the entrance to the profession be abolished. This is the first step towards an honest efficiency system that will discriminate against neither Trojan nor Tyrian. Call this socialistic if you will, but it is progressive and neither fanciful nor impossible. It may involve constant experimentation with new methods of investigation and examination, but progressive aims involve the responsibility of finding progressive men and devising progressive methods.

The present agitation in favor of group medicine, so-called, deserves a word. Heralded as a reform, it is really one of the many proliferations of medical imperialism that, in our present state of organization, threaten serious danger to all. To disguise such a system with the simplicity of an eternal verity and to deceive the people by this specious cry of "Better doctors for less money," ring no more true to sound ethical principles than the screaming posters, so offensive to the eye, that advertise the fake fire sale in our cheaper stores. If many of our important medical problems are to be solved by socializing our organization, as some believe they will be, then the fate of honest and efficient medical service and the fate of the good name of the general practitioner are linked with

the fate of a medical democracy. If group medicine is to be what it now pretends to be—better medical service, and not medical panhandling—it is an important instrument for the welfare of the people, and its success will be linked in large part with the efficient supervision maintained over it by wise and impartial medical leaders. This is the secret of the success of an institution in this country that is considered a model of the group medicine idea. Time and again men have tried to copy it only to meet with absolute failure because their eyes were focussed on a vast surgical clinic with its enormous financial returns. They failed to visualize the wisdom and the strength and the courage of the leadership that made a medical democracy the foundation of a marvelous efficiency. Its financial success therefore is resultant, not causative.

Although in the abstract, group medicine may be a good thing, in the concrete, if the members of your group are incompetent or dishonest, it is worse than the condition it hopes to remedy. Like inefficient schoolhouse inspection that rouses a community and causes the people to look to the man responsible only when a fire occurs and innocent children are burned to death, so inefficient or dishonest group medicine that results in some fatal mistake may fan the flame of moral indignation and cause us too late to wake up to the inefficiency of those responsible. It is the same question that is emblazoned on the walls of every hall of medicine. Who is responsible? A little foresight, a little social imagination, will prevent many a medical calamity if we will only recognize the importance of true medical preparedness, which first means the highest possible efficiency of those to whom we entrust fundamental responsibility. Such a progressive system of administration will stimulate each individual to make himself more efficient and then it will be easy to value him according to his merit. The cry of "better doctors for less money" will cease to make us blush, for with the dead wood eliminated, only those with superior qualifications will be found in responsible places, and the general man will be the last to complain.

At present the general practitioner has a just grievance, since the supporters of this new idea, besides praising it as a bargain suggest that it supplants his incompetency. With the advent of the medical bargain, the marked-down funeral will become popularized, and between them the casket trust will be vanquished. One group of these altruists offers to send back the patient to the general practitioner with copious reports and directions for treatment, but they make no mention of car-fare. With group medicine today there are treacherous possibilities. The layman with financial genius is given an opportunity to invade the field of medicine by establishing, forsooth, the Great Arctic and Antarctic Group Medicine Company, with offices in every city and large town. By buying cheap in the open market

quantities of group talent, he will be able to do a prosperous business on a small margin of profit. The young man just out of training will often, through financial distress, be drawn into this system and compelled to sell his skill and knowledge to the figurehead who is planted in the midst of rich mahogany. Rival firms will vie with each other in devising new ways of advertising, and medical ethics will die in the stranglehold of commercialism.

The general man's idea of efficient group medicine is consultation with—what now seems to be considered an old-fashioned institution—the learned internist. For him it is the original, most serviceable, true and tried method of seeking light in dark places. The good internist is worth a dozen groups and more. The misfortune is that there is not enough of him. The general man is always glad of his opinion, and if the surgeon and the specialist would consult with him more frequently, they would be saved from many a foolhardy venture. Never was he so much needed as he is to-day to deliver some of our specialists and surgeons of pride and covetousness and envy, and to encourage the general practitioner to stifle his bitterness and keep "his heart still pregnant with celestial fire." He it is who typifies the master mind in medicine, that ability in diagnosis acquired only by a life of ceaseless intellectual training, and that human sympathy which distinguishes only God's own gentlemen. To know him is to love him, and in the spirit of the tribute Dick Steele paid to Lady Elizabeth Hastings, "To love him is a liberal education." May the specialist soon learn to love him!

What the general man then demands is that surgeon and specialist be held up to a high standard of efficiency.—a standard at least half as high as they would require for him. Physicians, be they surgeons or specialists or general practitioners, are good or bad, honest or dishonest, cultured or not cultured, efficient or inefficient. These are the only recognized lines of social cleavage in a true medical democracy. Let us have social justice combined with old-fashioned culture and courtesy, and let us have more boosting up and less pulling down; because, in the language of a philosopher, "Intelligent self-sacrifice of the strong to the weak, makes the strong stronger and the weak more strong. To him that hath the capacity to receive shall be given the priceless boon of opportunity, and from him that hath not shall be taken away the power of degrading himself and society." The general man has had enough of gibes and insults, and "the spurs that patient merit of the unworthy takes." He is no longer a child in the go-cart. Like Ibsen's Nora, he is weary and disappointed in this doll's house that has been erected above him, and unless his brothers are willing to level it to its foundation, like Nora, too, his self-respect will compel him to leave many things that he cherishes and seek in his own way intellectual independence.

## Clinical Department.

### ANESTHESIA.\*

By EDWARD L. YOUNG, JR., M.D., BOSTON.

DURING the time from the first introduction of ether up to within a comparatively recent date, the art of anesthesia consisted mainly in rendering a person unconscious and if possible relaxed, and that part of any operation was performed by a subordinate, often the youngest man on the team, who had a very imperfect knowledge of the work. Within recent years more and more attention has been paid to this very important part of surgery, and not only has the standard of the etherizer been very much raised, but the means at his command, in methods and sequences of drugs, been greatly increased. Both because surgeons are realizing the importance of anesthesia and because in certain methods they have an active part in that process, they are coming in closer touch with the etherizer and with the various modifications he uses. But it is not enough to have a highly trained specialist at our command; we must know enough about the effects of the drugs to know what is best for our patient in any given operation; the details of administration we can leave to the man behind the cone. We must be willing to give a reason "for the faith that is in us," and so I am going to discuss here the drugs and sequences with which I am familiar in hospital and private practice.

First to enumerate some of the effects of the drugs on the human organism. Ether is an irritant to the respiratory tract; when the lungs are normal this irritant action expends itself on the mucous membranes of the larynx, trachea and upper bronchi with the production of an abnormal amount of mucus; but not always, for in a certain small percentage of cases there are, even in normal healthy adults, pneumonias following etherization which though perhaps not entirely due to ether, certainly would not have occurred without it. And in elderly people or anyone with damaged lungs this action of ether is of the greatest importance.

Ether is an irritant to the kidneys. In any series of cases carefully studied before and after operation, the urine will show evidence of renal disturbance, indicated by albumen and casts, in from five to twenty percent, of cases where supposedly normal kidneys were present. According to Miller's work the function of the kidneys is depressed following etherization in direct proportion to the amount of ether used; the decrease going from 9.9% with small amounts of ether to 26.3% where large amounts were used.

Ether first raises and then lowers blood pressure; it likewise acts for the first half hour as a stimulant and then as a depressant. Ether very markedly diminishes phagocytosis and the

agglutinating power of the blood. Ether has no harmful effect on the heart if rightly given; it is not contraindicated where cardiac lesions are present. Ether is disagreeable to take and is apt to be followed by a considerable degree of nausea which, aside from its discomfort, is not without danger in head cases and cases of increased blood pressure from any cause. The margin of safety with ether is very wide and it comes nearest of any of the general anesthetics to being "fool proof." The immediate mortality of ether is not far from one in five thousand in this country, according to collected statistics, and according to Hewitt, one in sixteen thousand in England. The higher mortality in this country may be attributed in part, at least, to the fact that any Tom, Dick, or Harry has been considered good enough to hold the cone.

Because of its low mortality and very wide margin of safety, ether is the anesthetic of election in the majority of routine surgical cases. Preliminary medication of a hyperdermic injection of morphine and atropine helps in a quieter and more rapid induction of unconsciousness. The use of gas to put the patient to sleep and then the substitution of ether is much easier for the patient, and in so far as it lessens the stage of excitement and the amount of ether used is likewise safer. A certain amount of rebreathing is probably necessary to preserve the  $\text{CO}_2$  balance in the blood, and whether or not we follow Yandell Henderson to his final conclusion and believe that the diminution of  $\text{CO}_2$  in the blood, apnoea as he calls it, is the cause of shock, clinical evidence proves that patients do better who do have the optimum amount of rebreathing. This does not mean that the drop method is to be dispensed with; in fact it gives one of the reasons for the obvious advantage of most face masks, namely, that just enough rebreathing goes on and not, as in most closed cones, far too much as well as periods of too great ether concentration. As with Henderson's theories, so with Crile's, we are not obliged to follow him in all of his experimental and theoretical details and conclusions in regard to anoxi-association, but the clinical facts seem beyond dispute; that when local as well as a general anesthetic is used, patients are better relaxed with less ether, there is less shock from the operation, and the post-operative course is much smoother.

Chloroform need not be discussed, as the cases in a well-equipped hospital, where a safer substitute cannot be found, are very few and far between.

Nitrous oxide gas can be used for all minor operations requiring but a very short time for their completion, and used as such, it is by far the safest anesthetic. Mixed with about eight percent of oxygen to prevent cyanosis, gas can be used for operations of any duration in the majority of individuals. Used in this way the gas and oxygen mixture presents the following conditions:

\* Read before the Fortnightly Surgical Club.

It is not irritating to the lungs or kidneys.

It has no bad effect on the heart except in so far as it causes cyanosis, in other words is poorly given or is administered to an unfit subject.

It tends to raise blood pressure slightly except at the end of long operations.

It is easy to take and recovery is quick and with few, if any, symptoms.

The margin of safety is very narrow.

The immediate mortality varies according to the skill with which it is given. In the hands of experts it has been very safe. Various men report very large numbers without a single death directly attributable to the anesthetic. But it is very easy to step out of the safety zone and in the hands of careless or inexperienced operators, the mortality, is, I believe, extremely high, far higher than any of the other anesthetics in general use. Up to the present time in Boston, I believe the mortality is well over one in a thousand. But unlike the conditions with chloroform, the dangers here are largely if not entirely avoidable, at least if we can believe the experience of certain men who use it almost exclusively. The one thing that is emphasized by these experts is the color of the patient; with the face a pink color, no accident can possibly happen, while the minute any cyanosis develops the danger zone is in sight. And this gives the clue to the limitation of the anesthetic; if the patient cannot be anesthetized satisfactorily without cyanosis, then he cannot be anesthetized safely with gas and oxygen alone. It is possible, however, to add a small amount of ether without any of the irritant effects of the drug, and yet with enough additional anesthetic effect so that the gas and oxygen need not be entirely abandoned and yet the patient kept pink. Any attempt to force the gas oxygen in the face of insufficient anesthesia and slight cyanosis, is very apt to result in increasing cyanosis and respiratory embarrassment, and if still persisted in, will result in sudden cessation of the respiration and then very quickly of the heart, both beyond the point of return. Preliminary medication is of the highest importance in securing the most satisfaction both in comfort to the patient, and especially in attaining complete anesthesia without danger. The amount of morphia varies from three doses of one-eighth of a grain at three quarter of one hour intervals, to three doses of one-sixth of a grain given in the same way. The last dose carries with it a moderate dose of atropine. The amount of morphia depends on no rule of thumb; the only thing is to give enough to have the patient distinctly drowsy when he comes to the operating room, and to do this the effect of the first and second injections must be watched and the next dose increased or decreased accordingly. The use of scopolamine is not necessary and certainly adds to the risk of anesthesia where the morphia alone just as surely decreases the risk. In fact, the morphia can well be used with any anesthetic with perfect

safety and a more satisfactory anesthesia. The use of the local anesthesia with the general, Crile's technique, is likewise of great assistance in the use of gas and oxygen as much less of the general anesthetic is necessary than where no local is used. Gas and oxygen anesthesia is indicated in all cases where there is any obvious lung irritation, or any reason to think there may be a latent lung process, as in surgical tuberculosis of any kind. In cases with severely damaged kidneys, it is likewise to be preferred. Contrary to the usual dictum, I believe it is the safest anesthetic in old men with "weak" lungs and atheromatous blood vessels, if there is also any marked kidney damage, and with increasing skill in administration, it may be the safest under any condition. At the present stage of development, it should not be used merely for comfort's sake, but only in the face of a definite indication and then only by a skilled anesthetist.

#### SPINAL ANESTHESIA.

This is of more limited use as it cannot safely be used above the level of the pelvis. The difficulties are in its administration and the danger lies in the spread of the drug upward along the cord, until it reaches and paralyzes important nerve roots. Clinically, this is manifested by an alarming fall in blood pressure with all the signs of serious collapse. According to Smith's work, if the origin of the dorsal sympathetics supplying the splanchnic area are hit, the danger arises. Beyond these immediate symptoms there have been no untoward late effects. The great advantage is that all stimuli to the brain are cut off and shock is much lessened. The mortality has been high, though no accurate figures are available and it needs a skilled man to administer it, and because the patient is not unconscious, psychic shock may be considerable in nervous people.

If the anesthetist gives the drug with the experimental facts of Smith's work in mind, the collapse can be almost entirely if not completely avoided, and the mortality brought within reasonable limits. The details of such an administration are as follows: The drug used is 5 per cent. novocain with adrenalin; the dose from  $1\frac{1}{4}$  cc. to  $1\frac{3}{4}$  cc.; the injection should be made not higher than the third lumbar interspace. The drug should be diluted with equal parts, or at most, with two parts of spinal fluid, and this mixture must be put in very slowly. The Trendelenberg position should not be used for at least ten minutes. In short, every attempt is made to localize the effect of the drug low in the canal. The patient can be either on his side or sitting up for the injection.

This is a very valuable form of anesthesia in a limited field. For cases of great vesical irritability needing cystoscopy, it is invaluable as the paralysis of the motor nerves allows of the maximum dilatation with safety as well as without sensation. In perineal prostatectomies it

can be used with perfect satisfaction to patient and surgeon. In amputations of the legs for gangrene in diabetes it is also indicated. It can of course be used for any operation coming within the field of anesthesia, but it should be reserved for those cases where a definite indication exists. Caudal anesthesia has no advantages over spinal and is more difficult to give.

#### LOCAL ANESTHESIA.

This form of anesthesia has gained in importance since the introduction of novocaine, which can be used in almost unlimited amounts in a one-half per cent. solution without any danger of toxic symptoms. Practically all the operations of surgery have been performed by some men, with the use of local anesthesia, and while that is not necessary or even desirable in the majority of cases, it shows what can be done. There is a definite and, as our skill increases, probably broadening class of cases in which local anesthesia is, or will, become the anesthetic of election. But here, as in spinal anesthesia, a conscious patient must be considered, and that fact alone contraindicates the use in individuals of a certain type. Considerable practice and patience are necessary to make this form of anesthesia a success. It is indicated today in all operations on the scrotum or its contents, as the nerves can be easily and completely blocked, and on very minor operations. Operations on the fingers can be easily performed by blocking the nerves at the base of the finger.

To summarize: A surgeon should make every attempt to pick out for each patient on whom he operates the right anesthetic, which should be given for a definite indication.

### THE TREATMENT OF PARESIS BY INTRA-VENTRICULAR INJECTIONS OF DIARSENOLIZED SERUM WITH PRESENTATION OF CASES.

By PHILIP COOMBS KNAFF, A.M., M.D., BOSTON.

*Visiting Physician for Diseases of the Nervous System,  
Boston City Hospital.*

A fairly large experience with the treatment of syphilitic affections of the central nervous system by intra-spinal injections of salvarsanized serum by the Swift-Ellis method and its modifications, begun in my service at the City Hospital by Dr. Sanborn about three years ago, has shown that in no other way have I ever obtained such constantly good results. This opinion has been reached from the study of about five hundred injections on over a hundred patients, with pretty constant benefits, with no bad ef-

fects other than a temporary increase of pain, except in one case that died suddenly soon after injection from causes not fully determined. Among these cases, of course, were a goodly number of paretics and cases of cerebral syphilis. Although many of these cerebral patients showed a very considerable improvement, I have never seen such striking benefit as in the spinal cases. I have seen tabetics, who could stand only by the support of two nurses when treatment was first begun, who after a few injections could walk several miles with an approximately normal gait. I have seen a patient, completely paraplegic, with total loss of control over the bladder and marked anesthesia, leave the hospital walking normally, with complete control of the bladder and with normal sensibility and reflexes after three injections. Such brilliant results I have not seen in cerebral cases.

My own experience is like that of most observers and has led me to accept the hypothesis that the action of salvarsan, and its substitutes—neosalvarsan and diarsenol—is most pronounced when it is exerted most directly upon the spirochaete, wherever may be its lair. I was therefore much interested to learn from Dr. Graeme Hammond of his attempts to accomplish this result and later to have a practical demonstration of the methods employed by him and Dr. Sharpe as reported by them a year ago,<sup>1</sup> and to see the benefits obtained in several cases which were shown me by him at the Post-graduate Hospital in New York.

Experiments seem to indicate that the cerebro-spinal fluid is subjected to some form of circulation or is not confined in a single cavity, but in separate enclosures in the cerebro-spinal canal. Not only does its physical and chemical constitution seem to differ in different parts of the cerebro-spinal axis, but if a substance be injected into it in one place it does not become gradually diffused through the whole fluid, but exerts only a local action near the point of injection, and is gradually eliminated from the fluid. Tilney,<sup>2</sup> for example, found that pigment injected into the veins was not much diffused through the cerebral cortex, and Goldmann,<sup>3</sup> that injections into the lumbar regions of the spinal canal were not fully carried up to the cortex. Symmers<sup>4</sup> went a step farther and found that solutions injected beneath the cerebral dura had much more difficulty in diffusing and were much more rapidly drained out of the cranium than if they were injected into the lateral ventricle. By any method of approach it is probable that some of the injected substance reaches the cortex, but not so fully or so completely as by the ventricular route.

Attempts have been made to obtain the action of salvarsan on the cerebral cortex in paresis by all of these routes. We are all familiar with the attempts to treat paresis by the intra-venous and intra-spinal methods, and I think that most will agree that, although our treatment is often

attended with some good results, it is not so satisfactory as is the treatment of spinal affections. Marinesco<sup>4</sup> and Cotton<sup>5</sup> have tried the injection of salvarsanized serum beneath the cerebral dura with considerable benefit. Hammond and Sharpe have given intra-ventricular injections to a number of patients with very considerable benefit and no bad results, one or more of their patients being able, after three injections, to return to a business which involved considerable mental application. Ballance<sup>6</sup> and Fister<sup>7</sup> had previously tried a similar method with fairly good results.

The operation is comparatively simple. A small trephine hole about half an inch in diameter is made just in front of the bregma and an inch to the right of the median line. The dura is then incised so as to give an opportunity to select a spot free from large cortical vessels and a blunt-pointed cannula is inserted downward and backward about six to seven centimeters into the lateral ventricle. Hammond has usually found the dura very thick and opaque, but such has not been my experience. Ten to twenty cubic centimeters of cerebro-spinal fluid is then slowly drained off and an equal amount of serum, containing .6 to .8 milligrams of salvarsan, neosalvarsan or diarsenol is allowed to flow in very slowly and gently. The wound is closed in the usual way. Subsequent injections are made directly through the scalp. Hammond does this under local anesthesia from novocaine, but I have preferred to etherize the patient again rather than run any risks. Hammond gives a second injection in two weeks and a third four weeks after the second. Neither of us has as yet seen any unpleasant results from the operation.

The first patient entered the hospital February 7. He was extremely demented and it was felt that nothing could be of much benefit. He was an Irish coal heaver of forty, barely able to read or write, who denied syphilis. For a year and a half he had been apathetic, dull, neglected his work and was careless and filthy. He was untrustworthy and uncommunicative. There was loss of sexual power. The pupils were unequal, irregular and usually did not react at all to light, although occasionally there was a very sluggish reaction. The left leg was spastic and the left knee-jerk lively, the right absent. The speech was slow and slurring, the hand-writing illegible. He was silly, apathetic and disoriented and could remember but little. He was somewhat euphoric and always felt "fine." The blood and spinal fluid gave a triple positive Wassermann reaction, the fluid showed no increase of pressure, a cell count of 25, positive globulin and a negative colloidal gold reaction.

On March 10 he was given an intraventricular injection of serum containing 0.6 mmg. of diarsenol. The ventricular fluid removed was contaminated with blood so that the usual tests could not be made, but a negative Wassermann was reported. Nine days later he was much brighter, recognized a nurse and called her by name, took more interest in what was going on, talked more clearly and

wanted to go home. The knee-jerks were lively, but unequal, and he wrote more legibly.

On March 29 the injection was repeated. The fluid removed showed a negative Wassermann, the cell count was 15, the globulin double positive, and the colloidal gold a paretic reaction. It also contained some large (plasma?) cells. After this he seemed still brighter, was interested in what was going on, talked cheerfully and more clearly, and the pupils reacted promptly. On April 3 he was discharged. Since then he has returned temporarily to his work and seems more reasonable at home.

The second patient was admitted March 2. He was a drug clerk of forty who had contracted syphilis eighteen years ago. He took medicine by the mouth for eight or nine months, and during the last two months he had had thirteen doses of diarsenol intravenously. For over a year he had complained of tremor and loss of memory, but under his recent treatment the memory had improved. The memory, however, was poor, he was a good deal disoriented, and he made many mistakes in simple calculations. There was a good deal of slurring of speech and the handwriting was characteristic. There was tremor of the tongue and hands, the reflexes were lively, and the pupils did not react to light. The blood and spinal fluid gave a triple positive Wassermann, the cell count was 84, the globulin triple positive and the colloidal gold suggestive.

He was given, March 15, 0.6 mmg. diarsenol in serum by injection into the lateral ventricle. After this he seemed considerably brighter; he did simple sums correctly, he remembered better, the tremor was less, and the pupils reacted promptly to light. On March 29 the injection was repeated, and he has continued to do well. The ventricular fluid removed at the time of the first injection showed a negative Wassermann, a cell count of 20, double positive globulin, and the colloidal gold showed the reaction of paresis. The fluid removed at the time of the second injection showed negative Wassermann, a cell count of 5, positive globulin, and a paretic reaction in the colloidal gold test.

It is too soon and our experience is too limited as yet to permit us to come to any conclusions as to the merits of this form of treatment. The operative procedure seems to be fairly safe and the risks are apparently slight. The changes in the physical signs,—the return of the knee-jerk, the reaction of the pupils to light,—are not often seen in paresis under treatment, and, taken in conjunction with the apparent general improvement encourage me to continue with this method.

In conclusion, I would express my gratitude to Drs. E. H. Nichols and G. P. Sanborn for their hearty coöperation.

**SUBSCRIPTION TERMS:** \$5.00 per year, in advance, postage paid, for the United States. \$6.50 per year for all foreign countries belonging to the Postal Union.

An editor will be in the editorial office daily, except Sunday, from twelve to one-thirty p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager.*

126 Massachusetts Ave., Corner Bay State St., Boston, Massachusetts.

## THE STATUS OF THE FEEBLE-MINDED QUESTION.

THE general interest in the question of the detection and of the disposition of the mentally defective has now assumed such large proportions that we are very likely to be led into the belief that the matter is quite a settled one, and that only the administrative parts remain to be carried out. Yet we are quite in the infancy of knowledge on this subject. We are entirely in the experimental stage. It is true that we no longer think of all mental states in terms of one amorphous mass. New divisions are continually being carved out as we differentiate one variety or one degree of mental invalidism from another. Indeed, progress thus far has been almost entirely in this direction. Until 1905, when Binet proposed his now famous scheme for determining and for separating the feeble-minded children from the normal children by comparing them with standards of

mental ability for each age, the feeble-minded question had no existence. Since this announcement the scheme and, indeed, the whole subject has aroused a tremendous interest. The momentum it has attained has, unfortunately, sucked into its path a great many unscientific persons. They expect too much of it, and overlook the vital points entirely. The Binet system is often utilized as a hard and fast rule to determine, not only the existence of mental deficiency, but also the quantity, even up to a fraction of a year. It is obvious that the mind is too flexible to allow of any such definiteness. A standard should be an aim not to be attained, otherwise progress in mental evolution will be overlooked. A scale that will determine and separate the feeble-minded from the normal, that will remove them from being impediments to the progress of the normal, and that will prevent the forcing of expensive educations on inviolated minds, must be preëminently a flexible one.

The Binet scale of measuring intelligence has undergone a great deal of modification, until now very few of the scales in use look like the original. Besides, most observers have constructed scales of their own, on the same principle but different in detail. Nearly all of them provide for a scoring method, whereby failures in problems that should be done at a certain age, and which would relegate the child to a lower mental age, are neutralized with credits for negotiating some of the problems given for a higher age. All of the methods aim to add to the range and to the adaptability of the questions, so that there will be more flexibility in their application. The very numbers of the modifications themselves demonstrated that none of them is everywhere applicable. Some of the tests are too easy, others too hard, still others too few, from which to make an intelligent determination. Many of the tests are merely hobbies of individual examiners. The more tests the more confusion there is. Furthermore, the Binet tests and their modifications were originally intended for children of one school type. They are not quite so applicable to the mixtures found in American schools. They have less applicability to children above school age. It is difficult to construct a Binet scale for the later years because the range of knowledge keeps ever widening.

Moreover, the difficulty of constructing a suitable measuring scale is further complicated

by the fact that only in the profoundly backward are all the faculties retarded. These hardly need a Binet scale to determine this question. There are higher grades of defectives rising to the normal, and even above, in whom the retardation is only partial, in one or more faculties; and in the others they may even excel. These children must be recognized, and their normal faculties brought out and perhaps measured. The practical and applied psychologist can aid in this work with his laboratory. Unless this is appreciated, such children may be relegated into the class of the unfit because they fail in some of the tests for their age, when in fact they may be geniuses in some special faculty. The later measuring scale methods aim at this very question. Whether material, physical or mental, true economy lies in picking out the good parts of a mass, no matter how small it is. Nothing good must be wasted merely because it is buried in the bad. This takes time. One sitting with a stereotyped measuring sheet, perhaps in the hands of the inexperienced, is not sufficient to make so important a determination.

On the other hand, it is important that some system, standardized periodically, and sufficiently flexible, be constructed in order that the many surveys undertaken should have some uniformity of principle, and in order that results can be read and interpreted alike everywhere. Those interested vitally in this problem, whether they are mental hygienists, health officials, school physicians, criminologists, or the like, ought to agree on a selection of the best of the many methods and plans already submitted, or the adoption of new ones. In this way would a vastly important question be on the high road to solution.

rails against such delays take heed lest he himself is unwittingly the offender. A little over-cautiousness in making diagnosis, too much manipulation of gut, a too meticulous technic, or a failure to cultivate ambidextrousness may turn the balance between life and death.

In the *British Medical Journal* for April 15, Dr. R. P. Rowlands calls attention to these dangers. He believes that the time used in employing a needle-holder is, as a rule, wasted time, and he pleads for simplification of the technic in every possible way, deploring the modern tendency to over-refinement of method. Rowlands does not think that the surgeon should take time during an operation to explain its steps to an onlooker, but rather wait until all is over.

In the May 6 issue of the same periodical Dr. Edward Harrison corroborates his colleague's remarks, and goes into some detail as to time-saving methods. He thinks perfection of co-operation among the hospital staff may accomplish wonders in this way, and recommends frequent drilling of the operating-room force. He suggests that surgeons take a course in sewing from some female relative to improve their speed and accuracy; another hint is the acquirement of the art of tying a knot with one hand. The self-threading needle and the round-pointed knife he speaks of as valuable time-saving adjuncts, and takes up the opening and closing of the abdomen for an appendectomy to illustrate the points.

It would be well for American surgeons, who as a whole are probably the speediest in the world, to exchange time-saving ideas; for even those which the metropolitan surgeon regards as the most inconsiderable may be valuable to surgeons in remote districts who are unable to attend large clinics, and who do not operate often enough to evolve them for themselves.

## THE TIME ELEMENT IN SURGERY.

WHILE few can sympathize with the mental attitude of the surgeon who works with one eye on the clock, as the saying is, it has probably been the experience of all to see valuable minutes going to waste in the operating room while waiting for preparations which should have been made before the first drop of anesthetic was given. But let the surgeon who

## A NEW BUILDING FOR THE MASSACHUSETTS COLLEGE OF PHARMACY.

THE Massachusetts College of Pharmacy is actively planning for a new building, to be erected on the fine site purchased a few years ago at the corner of Brookline and Longwood Avenues, Boston, very near the new buildings

of the Harvard Medical School, and in the great center of medical education and practice that is being developed in this part of Boston. The building, as shown, is to be of an impressive character, that will add much in the eyes of the general public to the dignity of the profession of pharmacy.

This College is in possession of an endowment amounting to \$240,000, but no part of the principal of this fund is to be used. The new building with its equipment, exclusive of its site, will cost in the neighborhood of \$200,000, of which a part is to be obtained by the sale of the present building and its site, and a part is being raised by a campaign now under way.

Dr. Frank Piper, chairman of the ways and means committee, announced at a recent meeting of his committee that he had received a gift of \$50,000 on condition that an amount sufficient to construct the building was secured. He also stated that the friend who made this large donation, while desiring to remain incognito for the present, had by his generosity practically assured the early beginning of work upon the new building.

#### MEDICAL ASPECTS OF THE MEXICAN SITUATION.

THE great European War has now lasted for nearly two years, and to the ordinary perception there is no immediate indication of its ending. Though many persons feel, or at least express, confidence in the manner of its termination, to impartial observers its outcome still seems as much as ever on the knees of the gods. Naturally, as members of a dispassionate pro-

fession and citizens of a neutral country, American physicians, whatever their personal sympathies, have been largely interested in the medical aspects of the great war. For this reason, the JOURNAL will continue, during the coming season, the publication of its column of European War notes, in which items of interest from this point of view will be presented from week to week.

The United States is now menaced, more acutely than at any time since April, 1914, with the incidence of a second Mexican War, which at the present writing seems likely of declaration within a short time. In the several states throughout the Union during the past week, the militia, or national guard, has been mobilized, with the demonstration of varying degrees of efficiency and preparedness. A number of these militia units have already been dispatched to the Mexican frontier. Whether or not this mobilization proves to be the precursor of actual war, the Mexican situation is not only of intense concern to all Americans, but in its medical aspects affords to the American profession matter of import for action, as well as observation. The occasion and opportunity have arrived when the medical corps of the army and navy, the medical officers of the national guard, and, in the event of extensive hostilities, civilian members of the profession will either demonstrate or fail to demonstrate their fitness to deal competently and creditably with the medical urgencies that arise in time of war; and it is most earnestly to be hoped and expected that this demonstration will be in every respect a credit to the American profession.

In its present issue the JOURNAL begins the publication of a column of Mexican notes dealing, after the analogy of the European War notes, with topics of medical concern connected with the Mexican situation. In another column of this issue of the JOURNAL is published also the recent announcement of the American Red Cross in connection with its activities in preparation for a possible Mexican War. Unlike law, medicine speaks with an even stronger and more authoritative voice in times of war than in times of peace; and in Mexico, as well as in Europe, the work of our profession will be not only to succor the injured, but to maintain the standards and purposes of civilization through the inevitable barbarisms of war.

## MEDICAL NOTES.

**AMERICAN MEDICAL ASSOCIATION.**—At the recent annual meeting of the American Medical Association, Dr. William J. Mayo of Rochester, Minn., was elected president in succession to Dr. Rupert Blue.

**ROYAL SOCIETY OF CANADA.**—Dr. A. B. Macallum, professor of physiology at the University of Toronto, has been elected president of the Royal Society of Canada.

**NATIONAL ECLECTIC MEDICAL ASSOCIATION.**—The annual meeting of the National Eclectic Medical Association was held at Cedar Point, Ohio, on June 23. Dr. W. E. Daniel, of Madison, S.D., was elected president for the ensuing year. The next convention is to be held at Nashville, Tenn., in 1917.

**POLIOMYELITIS IN BROOKLYN.**—According to the figures compiled by the Department of Health, there are now 114 verified cases of infantile paralysis in Brooklyn, practically all of them in the old South Brooklyn section. Eight cases were reported from Manhattan so far this month. The outbreak appears to be confined to infants and young children, less than 10% of the cases occurring in children over five years of age. While some of the cases recently reported are really old cases, whose onsets date from May, others are of recent development; the latest onset thus far reported is June 19. It was natural to suppose that the schools had a share in spreading the disease, but at the Department of Health it was stated that a careful investigation had failed to substantiate this view. It was pointed out that over 90% of the children were under school age; that the cases were not limited or even more prevalent in any one school district, and that they were not at all limited to children in the same classroom. Because of the relation alleged to exist between poliomyelitis and the stable fly, a survey has been made to determine whether the cases thus far reported are at all in the vicinity of stables. This part of the investigation is still in progress. In the mean time, the Sanitary Bureau is taking special pains to see that the manure in all of the stables in the affected districts is properly disposed of to prevent the breeding of flies. One case was reported to the Department from Staten Island. It is rather interesting to note that this case, like most of the Brooklyn cases, is also in an Italian district.

According to a bulletin issued by the Department of Health, thirty-seven additional cases of infantile paralysis were reported to the Department of Health on June 26, making a total to date of 183 cases in Brooklyn. A study of the situation indicates that the disease is spreading in a southerly direction and is invading the Parkville section, to the east of Bay Ridge. Of all the cases thus far reported, none of the pa-

tients are over eight years of age. There was a rumor current that the Department of Health planned to close the schools, but this was denied by Health Department officials.

From the figures compiled by the Department of Health, it appears that during the past week 12 deaths were reported from anterior poliomyelitis (infantile paralysis) in the Greater City. Eleven of these deaths occurred in the Borough of Brooklyn, almost as many as occurred in the entire city during the year 1915, when 13 deaths from this disease were reported for the entire year in the Greater City. There was nothing else noteworthy in the mortality from the other causes during the week.

There were 1311 deaths reported from all causes, as compared with 1277 reported during the corresponding week of last year, the respective rates being 12.24 and 12.22, a difference of 0.2 in the weekly rate, equivalent to an increase of only 2 deaths. The mortality of the contagious diseases, other than infantile paralysis, was lower during the past week than during the corresponding week last year. There was an appreciable decrease in the mortality from pulmonary tuberculosis, which, however, was to some extent offset by an increase in the deaths reported from the other tuberculosis diseases. The mortality of the degenerative diseases was heavier during the past week than during the week ending June 26, 1915. The inclement weather last week resulted in an increase in the number of deaths from bronchitis.

The death rate for the first 26 weeks of 1916 was 14.82, as compared with 15.10 for the first half of 1915.

In response to a call issued by Commissioner Emerson, a conference of experts was held at the Health Department on June 28 to discuss plans for the control of infantile paralysis in Brooklyn. With 23 new cases reported June 28, the total in Brooklyn during the present outbreak, has already amounted to 206 cases. At the conference it was decided to organize a special field force in Brooklyn under Dr. Simon Blatteis of the Department's Bureau of Preventable Diseases. Assisting Dr. Blatteis will be a special staff of medical inspectors, sanitary inspectors, nurses, and sanitary police, who will visit all cases daily and see that strict quarantine is maintained. Hereafter all the premises where a case of infantile paralysis exists will be placarded. The Department of Health has prepared a special pavilion at its Kingston Avenue Hospital where sufferers from infantile paralysis will be cared for by skilled specialists. The Department is organizing a special visiting staff of experts, including specialists in children's diseases, orthopedists and neurologists, who will assist the regular attending staff in caring for the little patients. Wherever complete isolation and proper nursing cannot be maintained in the homes, patients ill with infantile paralysis will be removed to the Health

Department's special pavilion just mentioned. The Health Department insists that a patient, in order to be allowed to remain at home, should have a separate room, separate toilet, a special person in attendance for nursing purposes, and facilities for the proper disposal of all discharges. Where these facilities cannot be provided, the Health Department will remove the patient to its hospital, where these and many other special facilities will be provided free of charge and where the best obtainable medical talent will be in attendance. The Department calls attention to the importance of general cleanliness in all communicable diseases. In infantile paralysis, not only should there be the highest possible degree of cleanliness in the home, but careful attention should also be paid to the proper disposal of all discharges from the patient, both nasal and bowel. The Department will see that all the infected homes are supplied with effective means of disinfecting both the personal clothing and household effects, with a view to limiting the spread of infection to others. A special meeting of experts was also held at the Department of Health on Friday afternoon at 2.30, and on Saturday, July 1, at 2 p.m., a meeting of Brooklyn physicians, living in the area affected by the present epidemic, was held at the Polhemus Memorial Clinic under the joint auspices of the Department of Health and the special Poliomyelitis Committee. On July 1, 53 new cases and 12 deaths of poliomyelitis were reported in New York, making a total of 59 deaths since the outbreak of the epidemic.

**LONDON DEATH RATES IN APRIL.**—Statistics recently published show that the total death rate of London in April, 1916, was 17.2 per thousand inhabitants living. Among the several districts and boroughs, the highest rate was 25, in Shoreditch, a populous East Side shum, and the lowest was 12.3, in Hampstead, a more open suburb on the north.

**BRITISH HONORS FOR PHYSICIANS.**—The British birthday honors, recently announced, contain the names of several notable physicians. Dr. Christopher Addison, M.P., formerly lecturer in anatomy at the medical schools of Charing Cross and St. Bartholomew's Hospital, is appointed a privy counselor, and the honor of knighthood is conferred on Mr. Francis Mark Farmer, dental surgeon to the London Hospital, on Dr. Armand Marc Ruffer, president of the sanitary maritime and foreign council of Egypt, and on Dr. Nestor Tirard. Dr. Tirard is professor of the principles and practice of medicine in King's College, and senior physician to King's College Hospital and commandant of the Third London General Hospital. As secretary of the pharmaceutical committee of the general medical council, he has been for twenty years medical editor of the *British Pharmacopoeia*.

**MEDICAL SURVEY OF BRAZIL.**—The Rockefeller Foundation last winter sent to Brazil to make a general medical survey of the southern part of that country, an international health commission, consisting of Dr. Richard M. Pearce of the University of Pennsylvania, Dr. Bailey K. Ashford, U. S. A., and Dr. John A. Ferrell. This commission has recently returned to the United States after spending in Brazil a period of about four months, devoted to a study of the Brazilian general education system, medical schools, hospitals, dispensaries and public health organization.

#### EUROPEAN WAR NOTES.

**SURGICAL UNIT TO THE CENTRAL POWERS.**—The American Physicians' Expeditions Committee has recently sent from New York the sixth surgical unit which it has dispatched during the course of the war to the Central Powers. This unit consists of six physicians and six nurses under command of Dr. Joseph I. Eastman of Indianapolis, professor of surgery at the University of Indiana. This expedition sailed from New York for Rotterdam aboard the *S. S. Ryndam*. Its destination is Austria.

**THE SANITARY REHABILITATION OF EAST PRUSSIA.**—In the issue of the *British Medical Journal* for June 10, is published an editorial account of the recently issued report of Professor Kirehner in behalf of the commission of which he was a member, which was sent to East Prussia after the first Russian invasion and again after the second. This report describes particularly the effect of these invasions upon the country and the methods by which the sanitary rehabilitation of the province was effected.

On August 20, 1914, the population was notified that the province must be evacuated. Many thousands streamed away and were cared for by the war organizations. Between August 26 and 28, Hindenburg's victory temporarily eased the pressure of the Russian armies, and the civil medical administration was set the task of restoring order to the ravaged province. Professor Kirehner found the conditions less serious than he expected. Alarmist rumors had spread through the press to the effect that at the battle of Tannenberg thousands of Russians had perished in the Masurian lakes. It was feared that all the drowned men and horses would poison the province. But, as a matter of fact, the lakes are far from Tannenberg, and no foundation for these rumors could be discovered. On the whole, there was little disorganization from the sanitary point of view. The dead had been properly buried, and even on the battlefields there was little trace of the recent past. The wells were in good condition, and the land was again being plowed. The sum of 20,000 marks was provided for the care of infants and the tuberculous; temporary hospitals were run up in place of those that had

been destroyed; 200 beds, with bedding, were supplied in a few days by the Red Cross; and the requisite number of doctors and chemists was also provided. But in October fresh Russian forces swept over the border, and the province had again to be evacuated. This time the Russians stayed longer, and devastated the country more thoroughly. When Professor Kirehner and his Commission returned to the province after the second Russian retreat, the country was ruined. It was estimated that 300 million marks would be required to restore the 36,000 houses which had been burnt. Russian prisoners were employed by the thousand in gangs of thirty to forty for three months. Trenches were filled up, wells were cleaned, and hospitals and other most necessary buildings were restored. The graves of the fallen were also attended to. By July, 1915, some 75% of the inhabitants had returned, but for lack of housing accommodation a considerable degree of overcrowding was unavoidable."

**BRITISH MEDICAL CASUALTIES IN THE BATTLE OF JUTLAND.**—It is officially announced that in the great naval battle of Jutland on May 31 and June 1, a total of twenty-three medical officers were lost among the killed. These included the fleet surgeons of the *Queen Mary*, the *Invincible*, the *Indefatigable*, the *Defence* and the *Black Prince*.

**DIRECTORY OF WAR RELIEF FUNDS.**—In response to recent inquiry, we are publishing herewith a brief directory of the more important American relief funds for the European War, with the address to which in each instance money contributions should be sent:

AMERICAN AMBULANCE HOSPITAL. Mrs. E. D. Brandegee, 82 Devonshire St., Boston.  
 AMERICAN FUND FOR FRENCH WOUNDED. Kidder, Peabody & Co., 115 Devonshire St., Boston.  
 AMERICAN RED CROSS, MASSACHUSETTS BRANCH. Mr. F. L. Higginson, Jr., 44 State St., Boston.  
 ARMENIAN RELIEF FUND. Mr. Henry D. Forbes, National Shawmut Bank, Boston.  
 BELGIAN RELIEF FUND. Mr. J. H. O'Neill, Federal Trust Co., 85 Devonshire St., Boston.  
 BRITISH IMPERIAL RELIEF FUND. Mr. Charles H. McIntyre, 18 Tremont St., Boston.  
 CANADIAN RELIEF FUND. Mrs. Lydia G. Raymond, 500 Boylston St., Boston.  
 EAST PRUSSIAN RELIEF FUND. Mr. L. M. Bartels, 99 Nassau St., New York, N. Y.  
 FRENCH ORPHANAGE FUND. Mr. Allen Forbes, State Street Trust Co., Boston.  
 GERMAN RELIEF FUND. Dr. Rudolph Hertz, 32 India St., Boston.  
 ITALIAN RELIEF FUND. Mr. William R. Thayer, 301 Boylston St., Boston.  
 LAFAYETTE FUND. Old Colony Trust Co., Boston, Mass.  
 NATIONAL ALLIED RELIEF FUND. Lee, Higginson & Co., 44 State St., Boston.  
 PRINCE OF WALES RELIEF FUND. Mr. R. M. Stuart Wortley, 25 Broad St., New York, N. Y.  
 POLISH RELIEF FUND. Mr. W. P. Blake, 27 Kilby St., Boston.  
 RUSSIAN RELIEF FUND. Mrs. Curtis Guild, 121 Marlborough St., Boston.  
 SERBIAN DISTRESS FUND. 555 Boylston St., Boston.  
 ALLIES' TOBACCO FUND. Bartlett Brothers & Co., 60 State St., Boston.

BELGIAN SOLDIERS' TOBACCO FUND. Bartlett Brothers & Co., 60 State St., Boston.

**WAR RELIEF FUNDS.**—On July 1 the totals of the principal New England relief funds for the European War reached the following amounts:

Massachusetts Red Cross .....	\$146,390.67
Belgian Fund .....	129,491.33
French Wounded Fund .....	90,655.29
Army Huts Fund .....	59,715.60
French Orphanage Fund .....	56,705.83
Polish Fund .....	38,203.72
Surgical Dressings Fund .....	36,964.87
Facial Hospital Fund .....	22,925.55

#### MEXICAN NOTES.

**PREVENTION OF TYPHUS INFECTION IN MEXICO.**—Perhaps the most immediate and important problem in connection with the Mexican situation, is to prevent the introduction of typhus infection, which is more or less endemic in Mexico, not only among the United States troops, but into the country at large through Mexican refugees who are now crossing the frontier in large numbers. The United States Public Health Service has already taken measures to secure this end and rigorous examination of all such persons will be made at stations along the boundary. With reference to maritime travel, the following orders have been issued to officers on duty at all United States quarantine stations.

"The following provisions will apply to vessels from Mexico arriving at a port of the United States south of the southern boundary of Maryland during the close quarantine season:

"1. Vessels from Progreso, Tuxpam, or Frontera, that have discharged or loaded cargo at sea and have not been alongside a wharf, have had no crew ashore, and carry no passengers, may be passed without fumigation or detention of crew or vessel, provided all are well upon arrival and the above provisions have been certified to by an accredited medical officer of the United States.

"2. Vessels from all other Mexican ports, and those from Progreso, Tuxpam, or Frontera that have not complied with the foregoing requirements shall be treated according to the provisions of paragraph 105, Service Regulations.

"Vessels from Colombia, Venezuela, or any other port of South America or the West Indies suspected of being infected with yellow fever shall be treated according to paragraph 105, Service Regulations."

**RED CROSS ACTIVITIES.**—In conjunction with the mobilization of the National Guard and the imminence of impending war in Mexico, the American Red Cross and its branches have undertaken immediate activities to discharge their duties in the field. On June 19, the United States Military Relief Committee of the New York Red Cross, meeting in New York City,

completed arrangements for the immediate dispatch of four Red Cross hospital units to the Mexican border. These units are already organized and will have a capacity of caring for 2,000 patients. For the immediate financing of these units \$100,000 are needed, of which \$89,000 have already been raised. Volunteers are available for the immediate formation of two more units, if needed. Over 600 nurses are enrolled and available for service.

Report from Washington on May 21 states that the National Red Cross is prepared to equip field units sufficient to do hospital service for an army of 100,000 men and will soon increase its capacity so that it could care for 250,000. Its chief deficiency at present is in field equipment.

**SURGICAL SUPPLIES FOR MEXICO.**—The preparation of surgical supplies for use by the United States Army and National Guard in Mexico has been undertaken by the surgical dressings committee of the National Civics Federation. In addition to its headquarters at the Peter Bent Brigham Hospital, subsidiary work rooms will be established elsewhere throughout the country and invitations have been extended to women to volunteer for work in the preparation of supplies.

**DENTISTRY FOR MASSACHUSETTS NATIONAL GUARD.**—The importance of sound teeth in the general health and efficiency of the soldier has been abundantly demonstrated in the present European War. In observance of this lesson therefore, steps were immediately taken upon the mobilization of the Massachusetts National Guard to inspect the teeth of soldiers in the troops prior to their acceptance for active service. This work was voluntarily undertaken by the staff of the Forsyth Dental Infirmary, of the Tufts Dental School, and of the Dental Clinic of the Carney Hospital. During the early days of mobilization, soldiers were sent from the camp at Framingham to the Forsyth Infirmary for treatment, which consisted chiefly in extraction, filling, and cleaning. Later this work was continued at Framingham by a large number of dentists from the above institutions, who went to the camp and devoted entire days to the work, while the physicians of the medical corps were engaged in the physical examination of recruits, the re-examination of enlisted men prior to their acceptance for Federal service, and the administration of smallpox vaccination and anti-typhoid inoculation. As a result, the Massachusetts troops, whose departure for the front is already under way, will be sent into the field in creditable physical condition; and particular praise is due, not only to the regularly appointed medical officers, but to the dental surgeons who thus volunteered their services for the welfare of the Massachusetts troops and for the credit of the profession.

**CASE OF TYPHOID FEVER IN FRAMINGHAM.**—The vigilance of Massachusetts medical officers

is evident by the discovery and prompt quarantine of one case of typhoid fever among the troops assembled in camp at Framingham. Sixteen other patients with minor diseases were detained in the camp hospital.

**NEW HAMPSHIRE HOSPITAL CORPS.**—Report from Concord, N. H., states that on June 22, the Adjutant General of that state was authorized to organize a field hospital corps for the fifth division of the National Guard. This corps will be immediately recruited and will be located at Manchester, N. H. It will consist of sixty-seven men in command of the major, captain and other officers. The field hospital which this corps will maintain will consist of 216 beds.

**DEFICIENCIES OF THE MEDICAL SERVICE.**—The recent mobilization of the National Guard, though on the whole creditable throughout the country, has revealed deficiencies in the medical service as well as in other branches of the organization. One of these is the insufficient number of surgeons allowed to each regiment. On a war footing of 1600 men, each regiment has but four surgeons, who, under conditions of field service in war, are obviously insufficient. In all foreign countries the allowed ratio is seven surgeons to 1000 men.

Another great deficiency of the medical service is its lack of organized sanitary units. Many states in the Union have no field hospitals or ambulance companies. The entire organized militia of the United States, which has a strength on paper of 120,000, possesses only twenty-eight field hospitals and only eighteen ambulance companies, and these organizations muster 852 commissioned officers and 4000 enlisted men. The states which are entirely lacking in these essential units are Alabama, Arizona, Arkansas, Delaware, Florida, Georgia, Kansas, Mississippi, Montana, New Mexico, North Dakota, Oregon, Utah, and West Virginia. At camps of instruction for sanitary bodies recently held under the auspices of the United States Army, 8000 officers and men from the entire country were in attendance. Of these, 304 were from Pennsylvania and 292 were from Massachusetts.

#### BOSTON AND NEW ENGLAND.

**THE WEEK'S DEATH RATE IN BOSTON.**—During the week ending July 1, 1916, there were 214 deaths reported, with a rate of 14.68 per 1,000 population, as compared with 158 and a rate of 11.01 for the corresponding week of last year. There were 37 deaths under 1 year, as compared with 18 last year, and 62 deaths over 60 years of age, against 49 last year.

During the week the number of cases of principal reportable diseases were: diphtheria, 41; scarlet fever, 21; measles, 226; whooping cough, 24; typhoid fever, 7; tuberculosis, 66.

Included in the above were the following

cases of non-residents: diphtheria, 7; scarlet fever, 1; measles, 2; tuberculosis, 4.

Total deaths from these diseases were: diphtheria, 4; scarlet fever, 1; measles, 4; typhoid fever, 1; tuberculosis, 17.

Included in the above were the following deaths of non-residents: diphtheria, 2; scarlet fever, 1; tuberculosis, 2.

### Massachusetts Medical Society.

ESSEX NORTH DISTRICT SOCIETY.—At the annual meeting of Essex North District Medical Society, on May 5, 1916, it was voted that the "Society instruct its councilors to urge the council of the Massachusetts Medical Society to use every legitimate means to procure an amendment to the Workmen's Compensation Act which will give the insured freedom of choice of medical attendance."

J. FORREST BURNHAM, *Secretary*.

99 Bradford St., Lawrence, Mass.

### Miscellany.

#### THE PAY CONSULTATION CLINIC AT THE MASSACHUSETTS GENERAL HOSPITAL.

Two reasons led to the establishment of the Pay Consultation Clinic which was opened at the Massachusetts General Hospital on January 25, 1916.

One was the desire to make the facilities and staff of a large general hospital available to the practitioner in his care of patients of moderate means. The other was to enable this group of patients to obtain the benefits of a complete range of skilled advice and expensive equipment, at a fee within their reach.

It is intended that both the family physician and his patient shall be benefited. If not accompanied by the doctor, the patient is required to bring a letter from him, which is a guarantee that the person to be admitted belongs in the group for which this clinic is intended. Experience with the eight hundred patients so far received, shows that the family physician is making legitimate use of the opportunity. Two or three patients outside of those "of moderate means" have been noted, but it is expected that even this small number will be reduced by the consideration of the doctor who asks for a diagnosis and advice.

After a sufficient number of visits have been made for the clinic physician to establish a diagnosis, a letter is sent to the family doctor summing up the opinions of the consultants, together with the evidence given by the X-Ray Department and laboratories.

The treatment that seems advisable to the consultant is suggested to the patient's physician. The patient is not treated, and after the diagnosis is made, he does not return except at the request of the family doctor.

Many cases have required the combined investigation of several specialists. The neurologist and roentgenologist are needed to reinforce the opinion of the internist, or the ophthalmologist and neurologist confirm the diagnosis of the surgeon in a cerebral case.

Each of the New England states has contributed its interesting and difficult cases to the total of over eight hundred patients, so far seen in the clinic. Instances of the value of combined opinions are easily given. A case of severe anemia required the combined observation, each from his own angle, of the physician, surgeon, roentgenologist, and technician to locate the cause as a bleeding ulcer of the rectum which had given no localizing or suggestive symptoms. Another example might be cited of a patient with indefinite signs, which were finally brought to a focus by the x-rays of the chest. In another case, the catheterizing of the ureters, with the bacteriological report and guinea-pig findings localized a final diagnosis as a tubercular right kidney.

The clinic seems to be a concrete expression of thoughts that have existed in the minds of some of the more progressive men in and outside of the profession of medicine.

Before the Consultation Clinic was established, the opinions of one hundred representative physicians and surgeons in and around Boston were ascertained regarding such a step. The sixty replies received endorsed the idea without exception.

Recently, fifty-nine replies have been received from letters sent to physicians who have sent cases to the clinic. One has considered it a failure; fifty-eight have found it of great help and expressed their appreciation of it, and ten of this number have made some minor suggestions by which the clinic could be made of still greater assistance to them.

#### AMERICAN RED CROSS PREPARATIONS

COL. JEFFERSON R. KEAN, Medical Corps, U.S.A., as Director General of Military Relief for the American Red Cross, made the following statement on June 25:—

"The most important work which has probably ever been undertaken by the American Red

Cross for the assistance of the Medical Service of the army, is now being done in the organization of base hospital units from the personnel of the larger civil hospitals in this country. These base hospitals, which embrace much of the best professional talent in the country, are intended to be transported on the outbreak of war to the seat of military operations, where they are located at the city which is selected to be the military base. One of these is needed for each 20,000 men brought into service. They receive the sick and wounded coming from the field hospitals at the front, and in them the wounded soldier in his journey to the rear first finds a comfortable bed and trained nurses. Thirteen base hospitals with skilled personnel are now organized and seven more are in process of organization.

Each base hospital is equipped to receive 500 patients. Although organized by the Red Cross, they are not administered by it, but when called into active service, pass under the exclusive authority of the War Department and become a part of its medical service. The medical officers are given military commissions in the Reserve Corps, and receive volunteer commissions when called into active service. The nurses, in the same way, belong to the Red Cross nursing service, and in time of war become a part of the army nurse corps.

The organization in time of peace of these large and complex units will place at the disposal of the government immediately on the outbreak of war organizations which it would require many weeks to create and equip, and offers our soldiers from the first the finest medical talent in the country. The following are the locations of these hospitals and the heads of their various services:

*Presbyterian Hospital, New York City.*—Director and Chief of Surgical Service, Dr. George E. Brewer; Principal Assistant, Dr. Alfred Stillman; Chief of Medical Service, Dr. Warfield T. Longcope; Chief of Laboratory Service, Dr. Karl M. Vogel; Chief Nurse, Miss Anna C. Maxwell.

*Mount Sinai Hospital, New York City.*—Director, Dr. N. E. Brill; Chief of Surgical Service, Dr. Howard Lillenthal; Chief of Medical Service, Dr. R. Weil; Chief of Laboratory Service, Dr. George Bachr; Chief Nurse, Miss Elizabeth A. Greener.

*Bellerue Hospital, New York City.*—Director and Chief of Surgical Service, Dr. George David Stewart; Chief of Medical Service, Dr. Van Horne Norrie; Chief of Laboratory Service, Dr. Charles Norris; Chief Nurse, Miss Clara D. Noyes.

*New York Hospital, New York City.*—Director and Chief of Surgical Service, Dr. Charles L. Gibson; Chief of Medical Service, Dr. Lewis A. Conner; Chief of Laboratory Service, Dr. William J. Elser; Chief Nurse, Miss M. H. Jordan.

*New York Post-Graduate Hospital, New York City.*—Director, Dr. Samuel Lloyd; Chief

of Surgical Service, Dr. Edward W. Peterson; Chief of Medical Service, Dr. Arthur F. Chace; Chief of Laboratory Service, Dr. Ward J. MacNeal; Chief Nurse, Miss Amy Patmore.

*Brooklyn, N. Y. For Navy.*—Director and Chief of Surgical Service, Dr. W. B. Brinsmade; Chief of Medical Service, Dr. Luther F. Warren; Chief of Laboratory Service, Dr. Robert F. Barber; Chief Nurse, Miss Frances van Ingen.

*Massachusetts General Hospital, Boston, Mass.*—Director, Dr. Frederic A. Washburn; Chief of Surgical Service, Dr. George W. W. Brewster; Chief of Medical Service, Dr. Richard C. Cabot; Chief of Laboratory Service, Dr. J. Homer Wright; Chief Nurse, Miss Sara E. Parsons.

*Boston City Hospital, Boston, Mass.*—Director, Dr. J. J. Dowling; Chief of Surgical Service, Dr. Edward H. Nichols; Chief of Medical Service, Dr. John Jenks Thomas; Chief of Laboratory Service, Dr. Ariel W. George; Chief Nurse, Miss Emma M. Nichols.

*Harvard University, Boston, Mass.*—Director and Chief of Surgical Service, Dr. Harvey Cushing; Chief of Medical Service, Dr. Roger I. Lee; Chief of Laboratory Service, Dr. Richard P. Strong; Chief Nurse, Miss Carrie M. Hall.

*Lakeside Hospital, Cleveland, O.*—Director, Dr. George W. Crile; Chief of Surgical Service, Dr. W. E. Lower; Chief of Medical Service, Dr. C. F. Hoover; Chief of Laboratory Service, Dr. H. T. Karsner; Chief Nurse, Miss Grace Allison.

*Rochester, N. Y.*—Director, Dr. John M. Swan; Chief of Surgical Service, Dr. C. W. Hemmington; Chief of Medical Service, Dr. William V. Ewers; Chief of Laboratory Service, Dr. C. C. Sutter; Chief Nurse, Miss Emma Jones; Assistant, Miss Jessica Heal.

*Johns Hopkins Hospital, Baltimore, Md.*—Director, Dr. Winford Smith; Chief of Surgical Service, Dr. J. M. T. Finney; Chief of Medical Service, Dr. T. C. Janeway; Chief of Laboratory Service, Dr. T. R. Boggs; Chief Nurse, Miss Bessie E. Baker.

*Harbor Hospital, Detroit, Mich.*—Director, Dr. Angus McLean; Chief of Surgical Service, Dr. C. D. Brooks; Chief of Medical Service, Dr. B. R. Shurly; Chief of Laboratory Service, Dr. P. M. Hickey; Chief Nurse, Miss Emily McLaughlin.

The generosity of Mr. Irving T. Bush, of the Bush Terminal, Brooklyn, who for the past two years has given spacious warehouse room to the American Red Cross for the storing, boxing and shipping of European war relief supplies, has again been splendidly manifested, for he has relieved the embarrassment of the Red Cross in regard to space for storing the equipment of the five base hospitals now being organized in New York in behalf of our army and navy, by offering storage room for three of these units at the Bush Terminal. This large space is in addition to the storehouse which Mr. Bush has furnished the Red Cross as a depot for its European supplies.

#### CERTAIN OCCUPATIONS AS CONTRIBUTING FACTORS TO DISEASES OF THE SKIN.\*

BY CHARLES J. WHITE, M.D., BOSTON.

*Edward Wigglesworth Professor of Dermatology in Harvard University.*

WITH the rapid movement of the modern world toward social betterment, there has been initiated a most commendable desire to help the workingman in many ways. Increased wages, shorter hours, and healthier homes and working places have been obtained, and, in addition to these benefits, the authorities, with the aid of the medical profession, have undertaken a systematic investigation of the laborer's occupation, in an endeavor to discover and to eradicate, in so far as is possible, the noxious elements of his daily work.

The study and knowledge of occupational diseases are not new themes in what has been called law-abiding Germany, nor in conservative England, but in our easy-going, lenient United States, enthusiasm and zeal toward this wholly proper branch of social welfare have been awakened rather slowly, and it is only within two years or so that even the Massachusetts General Hospital, which we like to regard as a most progressive institution, has seen fit to establish a bureau devoted wholly to the study and recording of this branch of medico-social work.

\* Delivered at the Harvard Medical School, February 27, 1916.

It is not our intention to say that doctors have not known for a long time, more or less, about a few diseases associated with or caused by certain occupations, for this would be a misleading assertion, but it seems fair to state that any intensive study of this special division of knowledge is of comparatively recent origin in this country. There is an exception to this general rule, however, in favor of the skin specialists, who for many years have studied the causes of certain baffling diseases with the greatest detail, and have recorded in their special books and periodicals many interesting and important facts. But general medicine has not bothered over-much about the doings of dermatologists, and it may be that the world has been a loser thereby.

It is my wish, therefore, in the brief hour at my disposal, to tell you in so far as I may, what dermatologists have learned about the skin in its relation to man's work. This is not an easy task, I assure you, for the facts are many and the time is short; and one must avoid falling into the error of reading a mere catalogue, which might be useful to a student, but would form dry material for a public recital.

In treating this really large subject, we must be systematic and divide up the whole question into subdivisions, and I think some of you at least will be surprised at the number of headings we shall develop.

### DISEASES OF THE TROPICS.

In the first place let us speak of the man, be he soldier or sailor or engineer or explorer or

doctor, or what not, whose duty calls him to the tropics. Every year, more or less, we at the Massachusetts General Hospital have the unpleasant duty of discovering a leper, and in almost every instance the pitiable victim has hailed from the warm countries of the earth or else has visited them in his work. I need not dwell upon the details of this disease, for you know somewhat concerning it. It has been our lot also to recognize and to treat a man suffering from frambœsia, or yaws, a disease which was for a long time confused with syphilis and not without reason, but modern science has discovered that both diseases owe their origin to a protozoan called the spirocheta, one taking artificial stains very faintly and the other being considerably longer and relatively more delicate—I refer to the spirocheta pallida of syphilis and the spirocheta pertenuis of yaws. We have also been fortunate enough to identify an active example of the so-called "oriental sore"—a disease which is indigenous to the northern coast of Africa, the eastern shores of the Mediterranean, and the lands watered by the Indian Ocean. This affection has almost as many names as it has places of origin, but at present we know that this much be-titled malady is due to a minute animal belonging to the same group as the plasmodium of malaria. If you will look at many Armenians in Boston you will perceive on their faces a large depressed scar, and this is the stigma of a past infection of "oriental sore"; but the case I have referred to is the only one, I believe, which has been observed in Boston in its active stage. Elephantiasis, which signifies a huge enlargement of a limb, as a rule, is another disease which can be acquired in the warm countries. We have the disease here, you know, following repeated attacks of inflammation of the connective tissue of the skin, as, for example, erysipelas—but in the tropics the disease is acquired from the bite of a mosquito which harbors the embryo of a worm known as the filaria sanguinis. In addition to these diseases, man may acquire special forms of ringworm which flourish mightily in the heat and moisture of the tropics, so that his body may become completely covered with the plant. Or again, the human foot may become, from an infection closely related to the actinomyces fungus, the seat of a great swelling and abscess formation to such an extent that amputation becomes a blessing. This is called Madura foot, and falls to the lot of some who live or work in the Near East. And, finally, there is a peculiar wart-like growth found in the valleys of the Andes and known as the verruca Peruviana—a disease which Dr. Strong and his colleagues studied in their expedition of 1914.

#### DISEASES DUE TO ABNORMAL TEMPERATURES AND ATMOSPHERES IN THE TEMPERATE ZONES.

In the second place we shall speak of diseases produced in the temperate zones by abnormal

conditions of heat, or cold, or moisture, or dryness.

*High Temperatures.* The stationary fireman, who constantly opens his furnace door to throw in coal may acquire a permanently red condition of his lower legs due to the frequent blasts of hot air which flash against his skin. The baker who opens his hot oven door to insert his loaves is apt to suffer from a distressing eczema of the arms. The foundryman who handles his molten metal is liable to severe burns from splashing drops or from sparks which fly when the cooling metal is hammered, and the blacksmith may suffer a similar injury. We all know of the many forms of accidental explosions to which the members of our fire department are liable. These are some of the examples of diseases due to heat.

*Low Temperatures.* On the other hand, we are familiar with the chilblains and frostbites which fall to the lot of those whose vocations expose them to severe or to continued cold. These are the chauffeurs, cabmen, policemen, freight crews, soldiers, sailors, cold storage men, quarriers, ice handlers, ice cream makers, soda fountain attendants, and many others. One of the striking hardships of the soldiers of the present war has been their lot of standing for hours, and even days, in the half frozen waters of the trenches. A curious cause of chilblains came to my notice the other day in the case of a young girl whose duty it was to pack chocolates day in and day out in a room unheated in winter and artificially chilled in summer, and through long hours this girl removed chocolates from a cold moving belt, upon which a blast of cold air was directed from above. The resulting cutaneous disability was not to be wondered at.

The humidity or the dryness of the surrounding atmosphere plays an important rôle in certain occupations. A laundress, stooping for hours over her washtubs in hot, dog-day weather, may find her face red and to a greater or smaller extent dotted with sage-like grains. This condition, which we term hydrocystoma, is due to the plugging of the mouths of the sweat ducts of the skin, and in the moist heat the perspiration, becoming excessive and not being able to reach the surface, backs up and forms chambers of fluid. As you know, certain processes in the manufacture of sugar must be conducted in superheated rooms, and in some men, subjected to this heat and moisture, boils are very apt to develop.

*Excessive Dryness.* The dryness of the atmosphere exercises an even greater part in the susceptibility of, or, perhaps more accurately stated, the sensitization of men's skin to the noxious elements of their labor. Perspiration contains a good deal of fat and in normal amounts means much more to our comfort than most of us realize. In our New England autumn and winter the air is very dry but craves moisture, and without our knowledge or

consent steals what it can from our skins. You know the result,—our hands and wrists and ankles chaf and crack and our skins prickle and tingle and we are uncomfortable. This dryness and consequent fissuring of the integument mean the breaking down of man's chief defense against the ever-present surrounding bacteria and the irritating substances of his existence, and often constitute the determining factor of disease or health; and in consequence we who see and treat many diseases of the skin dread the advent of fall and winter, for we know how difficult it becomes to treat our patients under these adverse and rather unconquerable circumstances. One of the things I would do if I had money would be to build a skin hospital, equipped with a large green-house, and in this favorable, warm, moist atmosphere I believe I could cure, or at least alleviate, some of the cutaneous ills of winter. As will be seen, therefore, most of us have to contend with atmospheric dryness for a certain part of the year, but the men whose paths lie in the far north, or the men whose lives are spent among high mountains, must endure these conditions the year round. You who have read the exciting tales of Arctic travel will recall the fact that these hardy travellers find it absolutely necessary to anoint the skin of their faces to preserve it from destruction. At this point it may not be out of place to refer to the similar drying effects of alkaline water, which the herdsmen and civil engineers and railroad construction men of our southwestern deserts have to endure. The African, the Indian, the Mexican can endure and withstand the desiccation of the desert wind and water because Nature has endowed them with greasy skins, but the Caucasian whose lot is cast in these climes is not to be envied.

**Increased Air Pressure.** High air pressure exerts its influence on the human skin as it does on other human organs, and we have noted in the victims of caisson disease a peculiar condition known as purpura. In other words, the men who are building our underground railways or are laying the foundations of our modern bridges and sky scrapers exhibit a tendency for the blood to be forced out of its normal channels into the surrounding tissues, thus leaving a temporary or permanent, indelible stain in the skin. This discoloration is blotchy and at first red, but on the lower legs of the older workmen this red tinge becomes a chocolate brown and remains as such indefinitely.

**Excessive Light.** You know that all light contains at least two distinct elements—the so-called heat rays and the so-called actinic rays. We have already described the effects of heat in speaking of the fireman, the baker, the foundryman, and, of course, there are other sufferers from this natural element; but now we want to refer to those who fall victims to what are called the chemical rays of light. You have all noted the peculiar skin of the hands, forearms

and especially the neck, of farmers and gardeners and trench diggers and fishermen and sailors—you have observed the brown color, the thickness, and in the case of the neck the deep creases and at times tortuous folds of the skin. These conditions are common, but in certain susceptible individuals the sun produces more important changes. The skin of the face, or the back of the hands, may become in places a still darker brown and rough and scaly—a condition which we call keratosis; and, as a further development, cancer may arise *de novo* or out of these localized keratoses. These changes are observed so often in seafaring men that the Germans have dubbed this stage "sailor's skin."

The most advanced illustration of this dermatitis actinica has been observed among the original x-ray workers, not the patients but the doctors and the manufacturers, and death has claimed many of these pioneers who have given up their lives in consequence of their unfortunate ignorance and zeal, while others are living today in delicate health, and crippled by the loss of one or many fingers, or even hands.

It is luckily well recognized today that the frequent worker with the x-ray must protect his skin well behind leaden screens if he would avoid the fate of his scientific predecessors. If he becomes careless, sooner or later he will perceive that his exposed skin is becoming reddened and then freckled, and that his hair is getting dry, and perhaps falling, and later that between the freckles the integument is growing white and thin and glazed and that little arborescent blood vessels are putting in an appearance. And later still, if this worker continues his unwise methods, he will observe rough, scaly, brown islands of skin, and in some weeks or months these isolated spots will grow hard and deep, and now he has developed cancer, often of a peculiarly malignant type. After this, ulcers form and scar tissue results, and then come the surgical operations—the ablations and amputations and deformities and disabilities, and you know the rest.

I have described in detail the blasting effects of unfiltered x-rays because I have witnessed every one of these cruel changes in quite a number of instances, but the same degenerations may result from the unwise use of radium or the Kromayer lamp, or from other unprotected forms of light. In regard to the ill effects observed in radium workers, it is interesting to note the conclusions just published by Dr. Ordway, until recently the head of our neighboring Huntington Hospital. This author and practised worker states that the chief objective changes in the skin consist of flattening of the characteristic ridges, thickening and scaling of the superficial layers, and even atrophy and intractable ulceration. Subjectively, the results are even more important and trying. Tenderness, throbbing pain and various other modifications of sensation are noted, and as in x-ray accidents, are curiously obstinate to control and

cure. Perhaps many of you have observed the strange figures sitting over our street railway tracks, helmeted and gloved, engaged in electric welding. Experience has taught these men what they must do to protect themselves. Strangely enough, there is a certain disease—fortunately one of our very rarest—where the victim is so susceptible to the actinic rays of the sun that all the various cutaneous degenerative gradations incident to repeated x-ray exposures are produced by mere existence in our everyday surroundings. We have observed at least seven of these miserable people in Boston—quite our share. The tendency naturally evinces itself in early life, and I remember one baby, taken out of doors for the first time in February, who became sunburned at once and then freckled and then developed the disease in all its hideousness. The actinic rays can produce another rare condition of the skin called hydroa aestivale, in which small water blisters form upon the ears and hands, and these peculiar individuals lead a handicapped existence, and may die in consequence of this strange idiosyncrasy.

#### DISEASES OF POSTURE.

The standing position, obligatory for so many of our wage-earners in trades and occupations, too numerous even to mention here, means, sooner or later, to a certain proportion of these men and women, varicose veins. I shall not speak of the pain and fatigue this common fault entails—that is not in my province today—but I must mention the ensuing deterioration of the neighboring skin and its consequent susceptibility to eczema and to bacterial infection—either of which misfortunes almost inevitably leads to the well-dreaded varicose ulcer—a condition which usually means weeks of incapacitation.

To the tuberculously inclined there is an added danger in the standing position, for young women of this type may acquire deep and painful nodes of the lower legs, which require, to effect a cure, months of the most favorable conditions of rest and hygiene, unless the patient is wise enough to submit at once to a surgical operation. This disease is known as erythema induratum.

There is one more disease of posture which should be mentioned before leaving this division of our subject. I refer to the calluses which tailors, cobblers and others acquire on parts of the body where there is constant pressure or where repeated blows fall.

#### VICTIMS OF INSECTS.

The occupations which expose men to the bites of insects are many, and the world is now cognizant of the fact that the bite of an insect may be a simple temporary incident or may carry in its train the germ of some fatal malady. Northern guides suffer most from mosquitoes, midges and black flies, and those of you

who have been attacked by swarms of these pests can appreciate what these men have to endure in their daily lives, in fact a peculiarly susceptible individual may die in consequence.

Gangs of laborers, huddled together in ill-kept shacks without bathing facilities and without means of frequent changes of body linen, may soon become infected with lice, bedbugs, fleas, or itch mites. All of these insects produce their characteristic bites or diseases entailing great discomfort or suffering and consequent diminution in the working capacity of their victims. Our northern lumbermen are perhaps the most frequent victims, but any group of men, women or children living under similar conditions may suffer the same consequences, and we must not forget to include here the teachers, the policemen, the hospital attendants, the nurses or the doctors who examine or treat these patients or their clothes, and not infrequently become infected.

Within the past decade or more a new disease has been discovered, due to the presence in the skin of the poisoned, dart-like hairs of the caterpillars of the brown-tail moth. These imported pests have necessitated a great increase in our forestry work, and many men employed in this capacity have been poisoned not only by the living insects but by their leafy nests, which harbor the noxious material. Still more recently Dr. Schamberg of Philadelphia has been able to prove that a type of red and itching skin, observed in millers, farmers, and packers, is due to the presence of a small mite called the pediculoides ventricosus in the flour and straw which these men handle, and to this disease Dr. Schamberg has given the name of grain-itch.

#### THE RÔLE OF CERTAIN VEGETABLE PARASITES.

There are several groups of parasites, higher in the vegetable kingdom than bacteria, which now deserve our attention. The commonest of these, the hyphomycetes, produce diseases known as ringworm and favus. All classes of children are liable to become infected with ringworm, and the children of eastern Europeans and northern Italians bring favus to this country and frequently escape the usually vigilant eyes of our health inspectors. Those who care for such children, nurses, teachers, parents, doctors, are often infected with these diseases. Children are not the only conveyers of these organisms, for our common domestic animals, the dogs, cats, mice, horses and cattle, harbor these plants and play an important part in their dissemination. Thus several large classes of men and women are affected—I refer to cat and dog fanciers, hostlers, coachmen, jockeys, farmers, cattlemen and veterinarians. As a rule, ringworm in the adult in this country is an unimportant malady, for it is easily detected and easily cured, but there is one exception, however, and that is in the case of the horse infection. The horse at times harbors a distinct variety of the plant, and un-

happy is the man who becomes infected with this type of the disease, for within a few days the hairy parts of the face begin to swell and in the course of a week or two become a swollen, distorted, painful mass of abscesses, from which pus literally drops in really large quantities. There is, curiously enough, a redeeming feature to this strange infection,—it is short lived. The plant seems to require for its sustenance a certain substance known as keratin and this food the hair of the beard supplies. The inflammation resulting from the presence of this type of the plant is so severe that the ensuing pus is so extraordinarily profuse that the hairs are actually floated away from their attachments in the skin and lost, and the plant dies from lack of nourishment. The result is a rapid and spontaneous relief from what at first looks like a terrible and destructive disease. In the end quiet is restored, the hair reappears and there are no scars to tell the tale.

There is another and rather indefinite group which affects men engaged in certain agricultural pursuits or who live in parts of the country where agriculture flourishes. I refer to the families known as actinomyces, blastomyces and sporothrix, and men who plant and garner grain and men who tend or slaughter cattle infected with these organisms fall victims to these usually serious maladies. Many of you, perchance, have heard of the disease actinomycosis or lumpy jaw. Here men and cattle develop multiple abscesses in the skin and underlying tissues and perhaps the internal organs, especially the lungs, become involved and the unfortunate victims die. It is the same with the other families, the blastomyces and sporothrix. Here again men are attacked, and so long as the organisms remain limited to the skin the patients can live. The blastomyces produce rather vegetative forms of skin eruption—the skin becomes ulcerated and the surface uneven, and pus develops and thick crusts form and there is a red-purple halo about the ulcer. This condition is extremely rare in Boston, although we have encountered two such cases; but it is not uncommon in Chicago and in the great Middle West drained by the Mississippi and Missouri river systems.

#### BACTERIAL DISEASES.

The bacterial diseases play a very large and important rôle in certain occupations.

Boils, as you know, are produced by a very common bacterium with a very long name, the staphylococcus, and boils fall to the lot of many a workman. The machinist whose skin and clothes are permeated with dirty oil is frequently affected. The skin of the sugar maker, whose particular sphere lies in the superheated rooms of the factory, becomes moistened and consequently softened and therefore an easy prey to the entrance of this pus-making organism, and this is the case with any workman who

spends his days in moist heat. The workers in aniline dyes, in mineral or metallic dust, in paraffin, in tar, and in chlorine gas are all liable to boils and are among the patients who consult us for this painful condition. Acute boils are painful but soon pass, but in some individuals, whose blood is not up to par, the disease becomes chronic and then life becomes trying and difficult and the ability to work becomes a question.

Tetanus or lockjaw at times falls to the lot of the man who digs much in country soil and to the carpenter or builder who may wound himself with rusty nails. The trench life of the present war has proved a fruitful source of infection to the soldier, and in the early days of the struggle many a poor man yielded up his life to this dread disease; but fortunately modern science has come to the aid of the present fighting man and to his peaceful brother and a special antitoxin, injected soon after the reception of a wound, means safety to the recipient.

Glanders, another often fatal disease, seems peculiarly associated with horses, and the man who tends them in any capacity is very liable to become infected whenever he comes in contact with such a diseased animal. There are so many varieties of livelihood gained by association with horses that this disease becomes an important occupational question.

Anthrax, or malignant pustule, a veritable scourge, lies in wait for the unfortunate victim whose occupation obliges him to handle the skins of animals. This seems to be peculiarly true of the hides and fleeces of our domestic animals and the freight handler, the wool sorter, or scourer or spinner, the tanner, the hair or bristle worker, the farmer and the butcher yield their annual quota to this dread disease. The spore of the germ of anthrax is most difficult to destroy, a fact which complicates the situation, and, in addition, no man has yet discovered an antidote to the poison. Curiously enough the greatest hope of cure lies in what in some other fields of human activity has fallen into obloquy—I mean watchful waiting. I shall never forget an experience of some ten years ago. I found in my hospital ward one morning a man in great pain. He sat propped up in bed and on his left breast was a large carbuncular looking mass the size of an orange. The center was black and crusted and surrounded by large, moist, bead-like, white pustules suggesting for all the world a giant brooch of hematite ringed by pearls. Beyond this the whole left chest and upper abdomen were swollen and hard and partly pink and partly blue—a most striking spectacle. The history was as follows: three morocco workers, to while away their lunch hour, made a ball of wet kid skin and passed it to one another. Within two or three days they fell ill and separated—one was treated at home and he died; one went to a hospital and the wound was laid open and he died; the third came to us and no knife touched him and he lived. This is not an

isolated instance, for we at the Massachusetts General Hospital have recognized that surgical interference in these cases usually means death.

Tuberculosis is, as you know, a frequent occupational disease. The good Samaritan, be he relative, nurse or doctor, who spends much time in caring for tuberculous individuals, frequently falls a victim to the disease. The surgeon, the pathologist, the anatomist, and at times the medical student, may become infected in the finger or hand while working upon tubercular tissue. The butcher and the cowman are frequently infected in their close association with cattle. In fact, you see, many vocations may lead, sooner or later, to this unhappy result.

#### ANIMAL PARASITES.

There is one disease to be mentioned somewhat apart from the ordinary bacterial diseases because we believe the cause of the affection to be nearer to the animal kingdom than to the vegetable. This disease is syphilis. Within a few years you have been taught that the innocent as well as the guilty fall a prey to this malady, which in its manifold and various ramifications engulfs many a poor victim. We physicians have been gradually learning that a large group of diseases of the heart and blood vessels, of the kidneys, of the liver, of the spleen, of the brain and of the spinal cord are in truth due to an early infection of the syphilitic virus. This is comparatively new knowledge, for up to within a few years we limited, more or less, the ravages of the disease to the skin, the bones, the teeth, the eyes and the ears, and suspected somewhat the brain. Perhaps some of you are wondering why this affection is included among the occupational diseases. It is because those who surely deserve a better fate not infrequently acquire the disease in the discharge of their professional duty,—I mean doctors and dentists and nurses and wet nurses, and it seems a still stranger irony of fate that these men and women above all others should be hit the hardest. At least two of my former doctor patients are now dead of this disease. In addition to this medical group of victims, the glass blowers, who take turns in using the blowing instruments, are once in a while infected by a fellow workman.

#### DISEASES OF OBSCURE ANIMAL ORIGIN.

We have heard a great deal, especially in the last two years, of foot and mouth disease among animals. We have read in the papers of the many cattle and hogs which have become infected and been ruthlessly slaughtered. We have noted with regret the loss of whole herds of prize dairy cattle belonging to people, and especially to women who had made individual pets of these valuable animals. We all regret this senseless loss of animal life and wealth, but seemingly at present it can't be helped be-

cause foot and mouth disease is perhaps the most contagious of all diseases among animals. Here again you may be puzzled at the inclusion of this disease in this lecture. Here and there in affected districts men who have dealt with the diseased animals have developed a peculiar malady in which their bodies and the inside of their mouths are covered with great water blisters which come and come, and sooner or later the man dies mysteriously. This disease, ultra rare when associated with epidemics of foot and mouth plague, but more commonly observed among butchers (especially in England), who have not come in contact with this specific affection, has been observed and commented on once at the Massachusetts General Hospital by Dr. Bowen. Dermatologists the world over have hunted for the cause of this human infection. They have found in more than one instance a so-called diplococcus and again a peculiar bacillus, but as yet the medical world is unconvinced as to the precise organism at fault.

Once in a while in the warmer months of the year the dermatologist notes at the hospital, or more rarely at his office, a peculiar redness and puffiness of a finger or of a hand, which resembles erysipelas but is not accompanied by the systemic disturbance usually associated with that disease—I mean there is no fever, no headache, no loss of appetite and no nausea. This strange condition resembles also what is known as a septic hand, but this well-known infectious process is associated with the presence of some of the common pus organisms, while the rarer disease now under discussion does not seem to harbor any bacteria. This abnormal condition is termed erysipeloid, and we encounter it in the hands of men who have come in contact with animal matter, in short, we meet it in fishermen, in lobstermen, in crabbers, in butchers, and in poultry handlers. Dr. Gilchrist of Baltimore has made a careful investigation of the subject as observed in nearly three hundred instances in the crabbers of Chesapeake Bay, and has come to the conclusion that the disease is not a bacterial infection, but rather a poisoning by certain putrefactive products of the animal caught, killed or dressed—in other words, a localized ptomaine poisoning.

#### PLANT POISONING.

There are a good many plants, some of them very common, which cause trouble to the human skin. The list is rather a long one, containing some sixty or seventy individuals, and includes poison ivy, poison oak, and poison dogwood or sumac, several varieties of primroses, the nettle plant, the vanilla bean, the cashew nut, cowhage, smartweed, balm of Gilead, rue and certain lilies, and in fact when an individual has once become sensitized to plant poison an inflammatory reaction often results from contact with any plant with a sticky juice. Perhaps many of you in this audience have experienced

the redness, swelling, and blistering associated with this distressing and at times temporarily crippling disease. It is, therefore unnecessary for me to refer to the rôle this condition may play in the lives of farmers, woodsmen, rural or suburban laborers and builders, nurserymen, and sellers of plants and flowers. It does not seem, therefore, out of place in this connection to sound once more a word of warning about the poisonous primroses. There used to be two kinds sold by our florists—the *primula obconica* and the *primula sinensis*. The former still deserves our attention because of the frequency of its victims. This plant was formerly easily identified by its large, dark green, spade-shaped leaf with its back covered with whitish, hairy spines; by its long slender, spine-covered stem; and by its cluster of small, lavender blossoms, six to eight in number. Nowadays identification has become difficult because florists have transformed the size and color of the leaf, the length of the stem and the size and color and number of the flowers; but the poisonous element has, unfortunately, not been eliminated. The law should forbid the future cultivation of this Chinese immigrant, but at present the rule adopted by the florists seems to be this: if the seller is not poisoned he continues to sell the plant; if the seller is susceptible to its venom he will no longer handle it and his customers are spared.

#### CHEMICAL IRRITATION.

We come now to the most important part, perhaps, of our theme, that is the great and frequent influence which chemical substances exert upon the men, women and children who, to earn a livelihood, are obliged to handle them. The number of cutaneous reactions produced is very numerous and too technical to describe: the list of chemicals capable of creating these damaging changes is too long even to enumerate, and the trades most often affected number between eighty and ninety to my own knowledge. The question then arises as to how this serious, almost everyday condition can be brought to your attention without wearying you by its very unwieldiness. I must, however, run this risk and take my chances with your patience.

The maker of acetylene gas may suffer from burns and ulcers due to the caustic lime in the calcium carbide.

The handler of denatured alcohol, and this means a large group of artisans, may suffer from eczema owing to the pyridine contained in methyl alcohol.

The aniline dye worker is liable to sweating of the hands, to redness, swelling and blisters of the skin, and to eczema as well, especially if he uses chlorinated lime to remove the traces of his day's work. Some years ago there was observed at the Massachusetts General Hospital, among members of the Boston Fire Department, a series of cases of skin poisoning which was easily laid at the door of a new issue of

shirts dyed with aniline black. Blaschko, a German dermatologist, has recorded similar results after contact with fifteen different aniline colors.

The handler of arsenic, be he the producer, the furrier, the taxidermist, the leather worker, the sprayer of trees, or what not, may suffer from redness and dryness and consequent itching, from pigmentation, from "shingles," from ulcers, from coriification and from cancer.

The artist at times may owe his eczema to the turpentine and various pigments associated with his profession.

The baker has to contend with the possible presence in the flour of the grain mite, with the irritation of moist dough and of saccharin solutions, and with the great heat of his oven, and is a man who frequently consults us because of his eczema. Other handlers of flour,—the miller, the grocer, and the cook, should also be mentioned in this connection.

The barber is subjected to many forms of irritation, for his hands are used on all sorts of people, rubbing in various soaps with hot and cold water, and applying all manner of patented hair tonics. Eczema, therefore, is not an infrequent disturber of this man's peace, and sooner or later may oblige him to abandon his calling altogether.

The bar tender frequently consults us because of his eczema produced by the constant submersion of his hands in cold and dirty water and in multitudinous alcoholic slops. Then, too, the brass, which must glitter in his establishment, requires frequent polishing, and this duty only adds fuel to the flames.

The bleachers and cleaners are peculiarly prone to eczema, for benzine, chloride of lime, various acids and gasoline all remove the natural fats from the skin and dry skins are always unfortunately susceptible to disease.

The borax workers may become eczematized, and this is true of the producers, of scrubbing men and women and of laundresses.

Bricklayers and masons have an occupation which subjects them to the constant use of water, lime, cement and mortar in hot and in cold weather and causes them to fall victims to a most obstinate type of eczema.

Brushmakers must scour the bristles with strong alkalis, and cutaneous irritation follows in a certain proportion of those engaged in this work.

Bronze workers are prone to eczema and to boils on account of their intimate contact with the dust of copper, with hydrochloric acid, with antimony sulphide and with benzine.

Calico printers handle many dyeing, mordanting, bleaching and cauterizing elements, and their potassium and sodium chromates, chalk and stannic and acetic acids are notoriously eczematizing.

The candy maker is a very frequent victim of eczema, for the hot sugar which enters so largely into this occupation is a determined irritant of the skin. To an even greater extent does choco-

late exert its pernicious influence on this group of sufferers, and the so-called chocolate dipper is a very frequent visitor to our skin clinics.

Canners owe their frequent attacks of eczema to the preservatives of the foods and to the ingredients used in sealing the tins.

Cabinet and piano makers, carpenters and in fact all wood workers, frequently ask us to cure their facial and manual eczemas. The resinous dust from many of the tropical woods, such as mahogany, rosewood, ebony, teak, satin and cococus; the variety of rhms, which enters into the elements of the Chinese and Japanese lacquers, and the pyridin, shellac, and methyl alcohol of their varnishes, form a large group of especially irritating substances.

Makers and handlers of drugs and chemicals suffer much and frequently from their occupation. Eczema, boils, acne, gangrene, ulcers, cancers and other diseases owe their origin to prolonged and frequent contact with such substances as arsenic, calcium chloride, cantharides, carbolic acid, the caustic alkalis and acids, chlorine, bichromate of potash, formalin, iodoform, mercury, opium, and tar. In this class are to be included the doctors, dentists, medical students, nurses, hospital attendants, and undertakers, whose vocations require the frequent use of bichloride of mercury and formalin.

Chimney sweeps suffer from a peculiar type of cancer engendered by the tarry products of the soot which permeate their clothes and bodies.

Cloth handlers may become eczematized by irritating wool fibers and by the various dyes which color them.

Cooks, scullery maids, dishwashers, housemaids, laundresses, house cleaners, in fact all domestic servants, are peculiarly prone to eczema of the hands and arms, for their work is wet and dirty and washing soda and other chemicals are employed frequently to lighten their labors, but often the result is disastrous. The dishwashers frequently present a peculiar infection about the nails called paronychia, and until recently the orthodox Jewish women suffered especially because their religion, which fears pork in any form, forbade the use of soaps, the fats of which might contaminate their eating utensils. Now, fortunately, Kosher soap has solved the problem and we see much less of Yiddish paronychia.

Coopers employ caustic soda to wash their barrels, and this chemical, plus the ensuing solution of the paints, sooner or later causes eczema in the susceptible.

Electroplaters, who employ lime in the cleaning of their metals, cyanide of potash, sulphate of nickel, and chlorine in a nascent state in their plating, and sour beer in their "scratch brushing"; silver polishers, who, in their work, depend on a rouge consisting of mercury, iron and wax and upon cyanide of potash and bichromate of potash, and, in their finishing, employ a mixture of lime dust and olive oil; enamelers,

who work constantly with various metals; and jewelers, whose work is somewhat similar to the others of this group, all follow trades which sooner or later may produce irritation of the skin.

Electric workers, who, day in and day out, subject their skins to lead, copper, brass, paraffin and various acids, fall a prey to these irritating substances.

Flax spinners suffer peculiarly from ulcers due to the constant handling of thread soaked in very hot water containing lactic and butyric acids.

Fruit preservers owe their frequent attacks of eczema to the irritating fruit acids and sugars and to the constant immersion of their hands in hot and cold water.

Furriers pay the penalties of their occupation more often than do most of their fellow workers. I have already spoken of the serious dangers of arsenic, and, in addition, these artisans may be affected by lime and by various dyes. It is not at all an infrequent occurrence for me to treat the victims of fur poisoning and the peculiar reddening and burning and itching and swelling of the skin at times are well nigh unbearable.

Galvanizers employ benzine, Vienna chalk and soap lye and dip their hands in the galvanizing baths and the results are frequently, temporarily at least, disabling.

Glass workers come in contact with copper sulphate and with hydrofluoric acid, and eczema often supervenes. The cementer of stained glass prepares and uses a substance composed of many eczematizing elements. This cement is compounded of ammonia, asphaltum, boiled oil, Portland cement, turpentine and whiting. What a list of offenders! It is no wonder that such a worker told me the other day that sooner or later, one by one, the men engaged in this particular division of the manufacture of stained glass had to be transferred to another branch of the work.

Gold refiners are irritated by cyanide of potash, and gilders are liable to a peculiar effect from turpentine which inflames their nostrils and gums and at times produces painful blisters and ulcers.

Hair dyers lead a life decidedly open to severe cutaneous irritation. The nitrate of silver and mercury and walnut juice of the older dyes and the paraphenylenediamin of the newer stains play havoc with susceptible skins, especially when they are moist, and the men and women who devote their lives to this sort of work must be really picked individuals, for not many weeks ever go by in my office without encountering some of the victims of hair dyes.

Hat makers suffer considerably from eczema, for fulminate of mercury, sulphuric acid, dirty water and the hair of animals are all irritating substances.

Men who handle hay, men who work with straw, men who use rushes of various sorts, may

suffer from unusual infections resulting from possible contaminating moulds.

Ice cream makers and soda fountain employees suffer from the effects of cold, as I have mentioned earlier this afternoon, but contact with irritating fruit acids adds its share to the hazards of these forms of employment.

Lacquer work is notoriously irritating. The poisonous oil obtained from the Chinese and Japanese rhus sooner or later may give rise to eczema, swelling, fever, catarrh of the eyes and nose or a popular outbreak on the arms and legs.

Laundry men and women are subject to continuous exposure to hot and cold water, strong soaps, soda, chlorine and many cleansing fluids, any one of which is capable of causing mischief to those with susceptible skins.

Leather workers, and this term comprises the makers of many articles of trade and commerce, and includes, of course, the tanners, have been mentioned before as possible victims of malignant pustule, but they may fall a prey also to the effects of arsenic, hydrochloric acid, lime, bichromate of potash and of the dye aurantia in which they work.

Linoleum, which in its various forms is coming more and more into vogue, requires crude naphtha in its manufacture, and this substance causes trouble to some of its users.

Lithographers, who make use of formalin in their "sheet printing," ask our help from time to time on account of eczema.

Masons and plasterers pay their toll to heat and cold as already mentioned, but they have to contend also with the eczematising character of the tools of their trade—the rough handles of their hammers, trowels and hods, made more irritating by the cutting edges of particles of granite and other hard stones. Then, too, their hands in winter are in cold water and in cement and lime and sand and hair, and the effects are often disastrous, as can be easily imagined.

Match makers deal with phosphorus and chromic acid and the sesquisulphide of sulphur, and these substances are very hard on those who handle them.

Machinists of all sorts have a common enemy in dirty oil, which is rubbed into and absorbed by the follicles of the skin, and if boils don't follow, eczema may. The necessary cleaning at the end of the day's work adds its quota to the harm to which these men's skins are subjected.

Metal workers, miners and smelters form another large class whose occupations subject them to many forms of irritation. Lead, mercury, copper, brass, bronze, antimony and arsenic are only a few of the more common minerals which produce various types of skin disease, but the concomitant dust, filings, acids, turpentine, etc., all form still further irritating adjuncts to these brands of human activity.

Mother-of-pearl, owing to its very fine, hard and gritty dust, produces a good deal of eczema.

Musicians, curiously enough, are subject to certain skin diseases. The persistent piano

player at times produces calluses on his fingers; the violinist, cellist and harpist and zither player follow his example; and the player of wind instruments may develop pressure symptoms on his lips. It was my ill fortune to observe recently a cancer on the lip of a saxophone player from this very cause, and this regrettable and serious condition represents, naturally, the extreme and fortunately rare limit of mischief which this constant daily pressure can produce.

Painters lead a really hazardous life. We are not concerned this afternoon with the evils of lead poisoning, but we must speak of the many cutaneous irritants of the painter's trade. In their white-washing their hands are soaked in water and lime and frequently irritated by the dirty accumulations of years which they remove from the walls. In their painting their skins come in contact with many poisonous mineral coloring matters, with grease and oils, and with turpentine, shellac, varnish and methyl alcohol. In the cleaning of painted walls and shellacked floors the modern patented fluids are full of potash and irritating oils. This makes a truly formidable list of enemies for any one group of men to withstand.

Paper hangers are subject to the irritating aniline dyes of their papers and to the harmful effects of the glues of their pastes. Fortunately for these men arsenic has been practically eliminated from their wares.

Paraffin workers seem to be peculiarly prone to skin diseases. The substance harbors, as you know, many provoking ingredients, mostly mineral oils, and constant contact with this medium, with the consequent impregnation of the clothes, may produce eczema, pustules, and in the end cutaneous cancer.

Paste, as just mentioned, contains glue, and consequently its makers and handlers may suffer from eczema.

Photography is a profession which supplies many a victim to the class of skin diseases we are now considering at such length. Metol, a comparatively recent developer, is a most common malefactor and bichromate of potash and of ammonium and pyrogallie acid are not much behind in their mischief-making qualities.

Physicians, and let us include here all those who handle and care for the sick, lead a decidedly hazardous existence. I have alluded before to the various forms of bacterial and animal life which beset the paths of medical men and women, but now we are concerned with chemical forms of cutaneous irritation. The constant washing of the hands, often with so harsh a substance as green soap, and the necessary use of chemicals, such as bichloride of mercury, tincture of iodine, alcohol, carbolic acid and especially formalin, lead to constant recurrence of eczema to such an extent that some of these victims are obliged to abandon a profession the preparation for which has cost years of time and hundreds and even thousands of dollars.

Porcelain makers have much to do with tur-

pentine, and you have noted this afternoon, perhaps, how often this substance enters into the various arts and have appreciated also its baleful influence on the human skin.

Printers engage in a trade notoriously trying to the skin. The lead of the type impregnates itself into the skin, and, owing to the danger of leaving this poison undisturbed, the man must clean his hands thoroughly before every meal. This process requires strong applications. Then, too, the preparation and subsequent cleaning of the type demands the use at one time or another of lye, oils, benzine, turpentine, acids and strong soaps—all mischievous articles with which we have now become familiar.

Stone cutters, be they the producers of the raw blocks at the quarries, the stone masons who help erect our buildings, or the sculptors who fashion our statues, suffer from the heavy work of their trade in their resultant calluses, from the sharp, cutting particles of stone which penetrate and subsequently poison the skin, and from the extremely irritating work of stone polishing.

Rubber workers, in one or more of the various steps in the manufacture of the raw material or of the many finished products, fall victims to eczema. The use of naphtha in all processes is most common, and the finisher uses a compound of benzine, shellac and ammonia,—a combination which drives many a patient to a skin doctor.

The miners of salt may suffer from ulcers, while men who handle salt, such as picklers, curers of fish and sausages, and ice cream makers, are liable to a peculiarly painful type of eczema.

The maker of shoes is a frequent sufferer from eczema due to the handling of leather (often very dirty), naphtha, soap and the chemical shoe polishes.

Sugar as a skin irritant has been implicated before in our reference to candy makers, but the manufacturer of the pure article suffers much from eczema, impetigo contagiosa, boils, lymphangitis, and sore finger nails. These various diseases owe their appearance to the possible presence of the sugar mite, to the inherent qualities of molasses and sugar, and to the great heat which is apparently necessary in certain steps of the making.

Tar handlers in the many and various phases of the term are peculiarly liable to skin diseases. Tar is used at times by physicians for its good effects in certain specific conditions, but this same substance is capable of great harm when brought in contact with the skin over too long periods of time. Pustules and acne are the first danger signals, and then come warts, various thickenings of the horny layer of the integument and finally cancers. We have noted this possible contingency before in speaking of chimney sweeps and paraffin handlers.

Tobacco workers come to our notice quite

often suffering from eczema of the fingers and hands. The tobacco leaf in itself is in all probability irritating to the susceptible skin, but in the process of manufacture certain caustics and the waters of fermentation add their quota of mischief to the original irritant.

This, then, closes my long résumé of the subject, and, looking back over these many subdivisions of the question, we may note that 46 or more diseases have been mentioned, apportioned among approximately 120 different occupations. This is rather a discomfiting disclosure to us perhaps, especially when we stop to consider that the past hour has been devoted only to diseases of the skin. However, we cannot dodge the truth of the foregoing remarks, for they are well recognized by men who have studied the matter conscientiously, and I personally have observed all but one of the diseases and have treated in all probability representatives of a very large proportion of the many occupations.

Let us not assume, however, that these diseases fall to the lot of all men and women who engage in these multifarious pursuits. That would be absurd; for if that were the case many of us here now would be at home nursing a damaged or diseased skin.

What, then, is the truth? There are no available statistics covering the whole subject of occupational skin diseases, but in the case of eczema we have more or less reliable figures. Knowles of Philadelphia reckons that one quarter of the cases of eczema which he treats are directly attributable to the occupation of the patient; Hazen of Washington computes the percentage at one-fifth, and Oppenheim, a German writer, makes the figures four-eighteenths; all three observers, you will perceive, in substantial agreement.

Granting, therefore, that a certain proportion of the community is susceptible to the dangers inherent in its chosen occupation, cannot anything be done to mitigate or possibly to abolish these dangers? My answer is a strong affirmative. How, then, can this highly desirable result be obtained? Mainly through the education of the employer and the employed. I for one do not believe that the average employer of labor is a brute and a tyrant, because, in the first place, in these days of keen competition it is not for his interest in any way to have his men incapacitated. One great object in the present intensive study of occupational diseases is to teach the employer in every possible way how to safeguard the health of those in his employ, and this purpose is slowly but surely being evolved. On the other hand, the splendid modern science of preventive medicine is gaining fresh impetus every day, and the results from the employer's point of view are already bearing fruit. We physicians, who spend our lives among contagious and often dangerous diseases, are fortunately usually spared from sharing the fate of our patients, mainly by our

knowledge of self-protection, and this same knowledge must be disseminated among all classes of our fellow-beings. That is what I mean, therefore, when I speak of a campaign of education; this is my purpose in appearing before you this afternoon; and this is the object the Harvard Medical School has in view in conducting over these several past years these series of free popular lectures.

### LEONARDO DA VINCI'S SCIENTIFIC RESEARCH, WITH PARTICULAR REFERENCE TO HIS INVESTIGATIONS OF THE VASCULAR SYSTEM.\*

BY ARNOLD C. KLEES, M.D., WASHINGTON, D. C.

(Concluded from page 7.)

With such an equipment, differing not essentially from our own, it is natural that Leonardo's findings had to be in advance of his time. For him "the heart is a muscle, the first in strength and the most potential among the other muscles." The ventricular as well as the auricular walls have transversal, longitudinal and oblique muscle fibres. He distinguishes the base and apex as we do, is aware that the base with fibrous, cartilaginous, osseous elements (the latter in animals) forms the more solid part of the structure, with which the more mobile elements, muscle fibres and valves are connected. He distinguishes the two ventricles and the two auricles, and he notes with precision their different shapes and the thickness of their walls. The septum is thinnest at the base and thickest at the apex. His conception of the septum, that part which has exerted probably the most important obstacle to a correct understanding of the cardiac function, naturally incites one's greatest curiosity, and it must be said that in the great number of representations Leonardo gives of it in various aspects, it does not appear materially different from what we know it to be. This is astonishing because in two or three places he speaks unmistakably about the penetrability of the septum in the Galenic sense, he names it the "cholatorio" of the blood, *i.e.* a colander, a strainer, but nowhere, not even in his schematic sketches, where one would especially expect it, does he show openings between the two ventricles.\* The question arises: what represents Leonardo's state of knowledge about this matter, his drawings or his words? A careful student of the manuscripts will be struck to find some expressions which could not possibly represent Leonardo's view, and still they stand there without any commentary. And then one will find else-

where the opposite view expressed, sometimes with direct reference to his own observations, the object of which may be further illuminated by a sketch. This gives one the impression that those improbable versions Leonardo perhaps put down on paper as a tentative proposition, a working hypothesis for further reference, and verification, and possibly derived from his book study. There are many other memoranda, the true nature and purposes of which are self-evident and therefore the supposition in this case may be allowed, *viz.*, that Leonardo, although he observed the solidity of the septum in the organs before him, noted down references to the literature. This reminds one somewhat of Vesalius' statement in the first edition (1543) of the *Fabrica* on this same subject, where he says that, although he did not find the holes, he, nevertheless, had to admire the Creator's skill which allowed the blood to sweat from the right into the left ventricle "through openings escaping the eye" (*meatus visum fugentes*). Sir Michael Foster, as you perhaps remember, considers this reservation as an ironical sneer, in no way an expression of doubt as to the solidity of the septum, but in view of the lengthy explanation which Vesalius gives of the same subject in the second edition twelve years later, his former statement may well be taken as an expression of uncertainty. Servetus' statement (1553) made between the two years, much more positive, may well have influenced him. As regards Leonardo, I may add that in one of his observations, undoubtedly his own here, he notes that he had found in one adult an opening (*foramen ovale*) in the auricular septum, and to be on the look-out for similar occurrences in other autopsies.

Leonardo's pictures of the external aspects of the heart are the best of his representations of organs: they might be compared with some modern ones, but with nothing from earlier periods. They have been criticized as not representing correctly the objects and also showing false relationship with adjoining organs (lungs, trachea). Both groups of objections are based on the presumption that Leonardo depicted human hearts, while it is clear that, particularly for the representation of the external features, he used bovine hearts and that he drew them perfectly correctly. As regards the correlation *in situ* it is true that there are several drawings which are evidently reconstructions by means of several drawings, which were derived partly from human, partly from animal objects. So in the much-admired large picture of a female situs, which must be considered as a most brilliant attempt at transparent anatomy, Leonardo draws the aortic arch situated in front of the left bronchus and below the bifurcation of the trachea, and from it issuing one large artery instead of three,\* all conditions found in bovines. It is clear that such a transposition of animal

\* In some sketches of sections through the septum, there appear on one side fine dots or short lines, but they do not reach to the other side. In the drawing of one square piece of the septum which shows on the upper and only visible side the unevenness of the surface, there appear on the cross-section several longer fine lines which, however, do not penetrate either (see *Quaderni II, fol. 3 recto*).

\* Elsewhere (*Foglietti B, 23 recto*) Leonardo shows the conditions as found in man, probably after he had had occasion to compare his earlier findings with those exhibited in a human autopsy.

anatomy into what purports to demonstrate human conditions is most misleading to the student, but in Leonardo's case it does not discredit the soundness of his actual knowledge any more than that of Vesalius' for drawing into his human figures the scaleni and recti muscles borrowed from dog anatomy. Leonardo did not intend his pictures for didactic purposes, and it is certainly more important to note that he drew correctly the junction of the vena azygos with the vena cava superior, also that of the venae spermaticae, the origin of both right and left arteriae sperm. int., and the relation of the ramifications of the hepatic blood vessels in the hilus of the liver to those of the hepatic veins in the liver itself, all conditions unknown in Leonardo's time (Holl, Quad. I, p. 80). Very lucid is his representation of the coronary vessels—"vessels which nourish the heart"—; he clearly distinguishes arteries from veins, they are uncovered except by a membrane ("pannicolo" *sc.* visceral pericardium). The artery lies deeper than the vein in general. In one view (Quad. II, 4 recto 9) one sees the origin of the two coronary arteries, their branches to the left and right of the pulmonary artery, the descending one of the right coronary artery running along the border of the right ventricle, this method of representation resembling much that employed in Henle's angiology (Fig. 1). In another view (Quad. II, 4 recto 3) we can follow the posterior vein of the left ventricle, the branches of the vena cordis media, the end of the vena cordis magna and its junction as coronary sinus with the inferior vena cava (Holl, Quad. II, p. 251). The whole coronary system is thus very well studied (Fig. 3).

FIG. 3.—One of Leonardo's many studies of the coronary vessels. Arteries are clearly distinguished from veins (A. cr. sup., V. cor. magn. and media), (from Quad. II, fol. 41).

The great vessels, both those issuing from or entering into the heart, on the whole, are well to be distinguished in these external views, in some they are left as short stumps, in others the aorta or pulmonary artery are cut off just above the valves. The absence of a marked conus arteriosus and of distinct auricular sinuses, which appear only as smaller dilated ends of the venae cavae or as auricular pouches at the entrance of

the pulmonary veins, is rather striking, but corresponds to the conditions found in bovines (Fig. 1). Not very clearly given is the entrance of the pulmonary veins into the heart (Fig. 4).

FIG. 4. Apparently the only sketch of L. II, which he indicates course and relation of pulm. veins together with those of VV. cavae. Note also "cholutorio" of septum, (from Quad. II, fol. 25.)

In one view they appear as a common trunk descending into the left ventricle with an auricular pouch, in another as two large vessels joining just before their entrance into the heart (Quad. II, 3 verso). But there cannot be any doubt about Leonardo's solid knowledge of all the parts of the heart, only as he examines them always with a view to their function, it is somewhat difficult to analyze them in the purely descriptive manner which modern anatomic research demands. Especially when it comes to an examination of Leonardo's conception of the valvular apparatus is it necessary to proceed in his own manner. Let us, therefore, see how he distinguishes the two sides of the heart. "The left\* ventricle has two orifices, one in the vena aorta, opening from within outwards, the other orifice is in the arteria venalis and goes from the heart to the lung, and has a single coat and is named arteria because of the thin (sottile) blood, and venal because of the simple vein (single coat)." On the same page we find the description of the right side, thus referring to his drawing: "—the gate of the lung (porta del polmone) and it is named vena arterialis; it is named vena, because it conveys the blood to the lung, and arterialis because it has two coats; and it has three valves (tre porte), which open from inside outward, with perfect tightness (perfecto serramento), and these are in the right ventricle, a the gate of the vena cava (vena chilj)." If we substitute for the Galenic terms, *i.e.* "arteria venalis and vena arterialis" our modern ones "pulmonary vein and artery": for "vena aorta" and "vena chilj," respectively aorta and

\* Leonardo writes here "right" evidently by mistake for "left", because in the same sentence he speaks of the aorta as issuing here (quad. II, 2 verso).

vena cava, remembering always that "vena" stood for "blood vessel" generally, while "arteria" signified literally then, as it does today, "air-tube," we have in the above a description corresponding to actual conditions. Leonardo also proceeds to a very painstaking examination of the valvular apparatus, to which he devotes several pages, one inscribed "Geography of the heart" (Quad. II, fol. 8 verso). Here again is strikingly apparent his mastery as a preparator and draughtsman. His examination embraces a careful scrutiny of all the component parts of the valves, separated, put together and *in situ*. One has the distinct impression that nothing escapes him and that he notes everything, and in passing I may call attention to one interesting discovery of his which was rediscovered only in our times. I mean certain muscle bundles or bands which traverse the ventricle from the ventricular wall to the septum, now usually described as "moderator bands" (Fig. 5). Leonardo was evidently much interested in these structures, as he draws them frequently in various aspects, and also in concordance with modern views he sees their function in the preven-

tion of ventricular overdistention,\* also interesting because of the great physiological and clinical significance only recently ascribed to the auriculo-ventricular bundles of His, which send branches into these bands of Leonardo's.\* To return to the valvular apparatus proper, it is obviously impossible to do justice to Leonardo's representation of them without going to very great lengths, and especially without an inspection of his many drawings. Most interesting and instructive is his preparation and demonstration of the tricuspid (Quad. II, fol. 3 recto and 8 verso). He dissects the whole valve from the underlying muscle, so that it appears unrolled in one plane or projection similar to that first employed in cosmographic projection by Mercator in 1550 (Fig. 6). We distinguish, issuing from the *columnae carnae* the papillary muscles, their *chordae tendinae* with their attachments to the cusps. The parts adjoining the septum and walls of the ventricle are indicated so that their position *in situ* is clear. "Join them together again," he notes with this drawing, "in the way they stand when the right ventricle shuts itself and then you will see the true shape of the valves how they do with their chordae when they shut themselves." And this is again illustrated in most original manner. In one picture we see the closed valve from the side of the ventricle, in the other from the atrium (Fig. 7). The mitral valve is studied in the same thorough manner as are also the semilunar valves as already alluded to above. The manner in which the aortic valve is shut engages Leonardo in various drawings. He studies the blood stream entering the aorta, the vortices which

FIG. 5.—One of many sketches showing the transverse muscle band. Note also indication of different thickness of ventricular walls. (from Quad. II, fol. 14r.)

\* "Li muscoli ramificanti . . . servono a non lasciare dilatare il core più che il dovere." (Quad. II, p. 12, fol. 4 verso V); in another note he speaks of them as "catena", i.e. brake (Quad. IV, p. 13). It must be noted here that these bands are much more distinct and also longer in bovines than in man, where they sometimes do not even exist as isolated bands. Helli, who has lately called attention to this discovery of Leonardo's, proposes to have these structures named after Leonardo, a good suggestion seconded by Sudhoff. (Quad. II, 8 verso, Figs. 1, 2, 3; 10 recto and elsewhere, also Quad. IV, p. 13.)

FIG. 6.—"Geography of the heart." Incisions on the pap. muscles, from left to right. "Modell. di r. ventricular wall, center, midwall." Note band which stretches from tricuspid, carn. on left to septum on right; also excellent representation of insertion of chord. tend. to cusps. (from Quad. II, fol. 8v.)

form beyond the valve and in the sinus Valsalvæ, distending and adapting the segments of the valve. To get a clearer picture of the valve he makes a cast of it in wax (Fig. 2, see page 61; he also seems to have used, or at least projected, a model of this region, a tube with a dilated portion so arranged that he could observe through a glass

FIG. 2. Description reads: "Simple valve without chordæ valve seen from inside." (from Quad. II, fol. 8v.)

window the behavior of a fluid in motion. By these means he demonstrates how the shock of the vortices, as well as that of the whole blood column in the aorta upon the closure of the valve, have to be borne, not solely by the valvular segments, but also by the adjoining parts of the ventricle and the walls of the aorta in the sinus Valsalvæ, thus preventing rupture.

The function of the heart as a propulsing motor for the blood is also very fully gone into. Horizontal cross sections through the heart, as well as longitudinal ones, are drawn (Quad. II, 4 verso, and Rav. Moll. Mss. G. 1 verso) during systole and diastole. From these drawings and accompanying notes it is evident that he understood perfectly the rôle of the ventricular systole and diastole; moreover, he was equally well aware that the auricular systole was not synchronous with the ventricular one (Quad. f. 4 v.) but that they alternated. On the other hand, he knew the synchronism of the ventricular systole, of the heart beat against the chest wall, of the entrance of the blood into the auricle and that of the arterial pulse beat; also that the sound produced by the shutting of the valve is transmitted through all the arteries to the periphery, and sometimes can be perceived in the ear. He attempts to fix the rhythm of the heart contractions; "after the systole follows the diastole in two-thirds of a harmonic (musical) tempo" (Quad. II, 11 recto, IV), and in measuring the velocity of the blood current—a modern physiological problem—he realizes that it is inversely proportional to the calibre of the vessels.

Before I attempt to sum up Leonardo's concepts about the blood current in general it is necessary to survey briefly some of his findings

in the lungs and in the general vascular system. Leonardo, here as elsewhere, proceeds by objective investigation and experiment, a fact which must be borne in mind when considering this survey, which is apodictic for brevity's sake only. The lung, the form and divisions of which he describes in detail, is an elastic organ, which adapts itself exactly (Quad. IV, 3 recto) to the chest walls and the diaphragm.\* It expands in every direction but more downwards "because more useful for the expulsion of food from the stomach." "The freshness of the air, entering the lung is taken up by the arteries, which are in continuous contact with the ramifications of the bronchi throughout the lung" (Quad. II, 11 recto), he gives a very interesting sketch, showing the relation of blood vessels and bronchi (Quad. II, fol. 1 verso). Near this picture are the following words: "To me it seems impossible that any air can penetrate into the heart through the bronchi,"† and he proceeds: "... the bronchi (trachea) ramify, dividing into minutest branches, together with the minutest ramifications of the blood vessels (vene), which accompany them in closest contact to the end." And then he asks himself, after having above excluded the possibility of the air entering the heart from the trachea and from its ramifications, whether "here the air enclosed in this (the terminal bronchi) blows ('spiri') through the fine branches, entering into the smallest branches of those veins." The final result of this highly interesting inquiry we do not know. He speaks of terminal bulgings of the bronchi, which Hüll seems inclined to consider as a primitive conception of the alveoli, but the important thing is that the lung as a respiratory organ is correctly conceived by Leonardo as a distinct anatomic unit, the bronchial tree with its blind ending branches in closest contact with the blood vessels (Fig. 8). We see that he places the interrogation mark at the very point where only some new technical device (microscope) can give the answer. As regards the general vascular system his drawings show, as elsewhere, excellent dissection of the objects, faithful rendering in drawing and a good conception of the relations between the blood vessels and the various organs. So we find his representation of the portal venous system in good accord with conditions found.‡ Excellent knowledge betokens his picture of the arterial and venous ramifications in the liver and those of the hepatic duct, which he represents issuing from the hilus and connected with the cystic duct from the gall-bladder.

The question now naturally occurs: What did

\* S. a. Quad. II, fol. 1, recto, paragraph 6, where he speaks of inspiration of the lung: "and never does it burst, as it never fills itself entirely with the air," plain words for an important physiologic concept.

† "Trachea" in the text, but the sense is evident. To be noted is particularly the lacking distinction here made between air-conveying and blood-carrying vessels, although in the same paragraph he says clearly: "The lung cannot send air into the heart," giving his reason why it is not necessary that it should.

‡ Except for one short venous trunk from Vena cava inferior as junction point for the portal vein and the vena lienalis (Hüll).

Leonardo know of the circulation of the blood as this phenomenon now stands in our conceptions? By students of Leonardo's manuscripts it has been variously answered. Holl, the most eminent and painstaking among them, holds the conservative point of view, believing that the material in hand does not allow a definite statement; that Leonardo was, however, on the right

FIG. 8. Most interesting representation (schematic but not phantastic) of the bronchial tree with blood-vessels. Note the circumscribed area in lowest part of lung. L. describes it as an irregular locus of debris; "Nature avoids the breaking of the tracheal ramifications" (from quad. II, fol. 1r.)

road. Boruttan, Roth and others, judging mainly from Leonardo's text, believe that he had not even a primitive notion of the subject and similarly opinions undulate between excessive affirmation and complete negation. It seems to me that it is *au fond* entirely irrelevant whether Leonardo thought on this subject as we do or not. In this matter, as in so many, we forget that the concept of the circulation of the blood is not a final, eternal one, but simply the best working hypothesis, at the present mo-

ment, for our purposes as we understand them, and which again are not immutable in larger human experience. But while we have no other measure than our concepts of today for those of yesterday, it is well to remember that Leonardo's definitive views on this subject are not before us for scrutiny. Fragmentary, unconnected (or at least not systematically connected) observations in a life's experience which in itself is fragmentary, as far as our knowledge of it is concerned. Take these sheets that we are analyzing to find Leonardo's final concepts and compare them to loose sheets torn out indiscriminately from the laboratory records of a modern worker, a Pasteur, a Koch, for instance. That illustrates the difficulties in store for us. But with all these difficulties we can see enough of Leonardo's method of procedure and the stages of his knowledge to realize that he was far ahead of anyone at his time, but that by it and through it he had to come essentially to conclusions very similar, if not identical, to ours. Two errors of his time stood in Leonardo's way toward a conception of the circulation,—the penetrability of the septum and the conveyance of air through the arterial system. The conclusion drawn was that the right heart conveyed the blood to the organs it nourished, receiving it back again by the same route it had taken, while the left heart, receiving the vital principle from the lungs and partly through the septum from the right heart, distributed it to the brain and all the other parts of the body by means of the arteries. Now let us take the essence of this teaching which had reached Leonardo from Aristotle, through the Alexandrians and Galen and their numerous commentators. The heart is the central organ of propulsion, from it the blood is actively thrown into all the parts of the body which it nourishes and these same parts are vivified by something conveyed to them by the arteries. (For the present it does not matter whether the blood originates in the liver, or the heart or elsewhere). As a working hypothesis this conception is quite acceptable, and the one thing that troubles us most is that "vital principle," for with it arise in our memories those different kinds of spirits, natural, vital and animal, which we like to convey into a museum of ancient superstitions or of mediaeval demonology. But did not our great Harvey say: "*neque sanguis sine spiritu sanguis est, sed acquirova et cruor*," just as a stony, dead hand is not really a hand; so "*ne sanguis sine spiritu vitalis sanguis* (Letter to Riolanus, 1619, p. 117). and did he not also frequently allude to its astral relation, as, for instance, in: "*spiritus nempe et ual ara in a spiritu respondens elementa stellarum*. And still we are all agreed that Harvey did discover the circulation. But Harvey came with his discovery one hundred years after Leonardo was dead, and for him the *spiritus in sanguine* might be conceded to be a *façon de parler* for our oxygen. Let us go back a little to the genial discoverer of the lesser circulation—

which, as you remember, Huxley does not grant to be a circulation any more than he would apply that term to a walk from his door to that of his neighbors—to Servetus, who puts it: "*Primum spiritus ergo est sanguis.*" You see the shifting of terms: the *sanguineus spiritus* here to the "spirituous blood" of Harvey. We can follow this same concept through all the historical competitors for Harvey's place,—Vesalius, Realdo Colombo, Cesalpino, Ruini, Sarpi and the vast mediaeval and Renaissance literature, a reminiscence from Alexandria, which produced that troublesome concept of the "*pneuma*," that "aeriform fluid" conveyor of sensation and nourishment that no one, including Galen, well understood, but nevertheless commented, dilated and "improved" upon, thereby eluding the more rational concept of the great Aristotle. The intellectual visions produced were the air-filled arteries, which every barber in Alexandria and elsewhere knew to spurt blood on incision, but which none-the-less held their sway in untroubled spiritual airiness throughout successive learned books copied from each other. It must be presumed that in those times, as in ours, there were sober men who read between the lines as well as on them, and who compared reality with literature, knowing the truth even if they had not the means to express it, or perhaps because they had not. A man, extremely proficient in hydraulics, theoretically as well as practically, Leonardo who wrote (Rav. Mss. II. 101 verso): "The water which from the extreme profundity of the sea rises through the strength of its motor to the heights of the mountain, finds there open veins, enters them, returning by the shortest way to the deeper sea '*ramificante vene*' again to rise. . . forwards and backwards. . . "*moto girando*"—could he really have completely ignored the course of the blood current in the body? It is on this point that we have from his hand no definite and sometimes contradictory information. We cannot entirely ignore his statements about the direct communication between the ventricles, neither his reference to the flow and ebb of the blood, but it is entirely permissible to consider such expressions not as conclusive, even if we do not find contrary views definitively stated. At any rate, wherever he mentions the flow and ebb motion of the blood both the ventricles and auricles are considered the motive force behind it (Quad. I, 7 recto) and although he nowhere describes the exact route by which the blood returns to the heart from the lungs after having described correctly the path it took from the heart into the finest ramifications of the pulmonary vein, it is significant that he asks the question: "Whether the vessels of the lungs do not send the blood back to the heart, when they contract to expulse the air?" Another sheet, one of the many lost, may have contained an answer which would have made clearer a further advance, such as his drawings,

considered by themselves, allow us to suppose that he must have reached. Being unable to assert with certitude what conclusion on this subject, as on others, Leonardo reached, it is, nevertheless, clear that he pursued methods of research essentially the same as ours. He did not publish these methods and conclusions in the conventional way, but we know that there were many other ways open by which he could reach his contemporaries. His teaching in his academy in Milan and the dissemination of his manuscripts, their frequent perusal by others, even during his lifetime, must have encountered receptive minds. So we study in him the silent, unheralded influence in the search after truth by the accident of the discovery of his manuscripts. His work and similar other influences fill the gaps in our historic perception, and I see herein their main significance, that by their realization we get a truer picture of the continuity of the evolution of scientific thought. And what makes the personality of Leonardo so interesting and sympathetic to us is not measurable by the close approximation of his anatomic and physiologic knowledge to ours, it lies much more in the identity of procedure in his scientific inquiry. He is much more like one of us than any of the brilliant row of scientific celebrities of past centuries whose prejudices we cannot understand. But, while identical as far as scientific procedure is concerned, I believe there are some elements in his wider aim, in his emancipation from too close specialization, where he might well teach us many things, the appreciation of which may well be left to each one of us, according to our individual lights.

## BIBLIOGRAPHY.

## Facsimile reproductions of Leonardo's manuscripts:

1. I manoscritti di Leonardo da Vinci della r. biblioteca di Windsor. *Dell'anatomia fogli A e B*. Two volumes, folio. Paris, E. Rouveyre, 1898, and Turin, 1901. This edition published by Th. Sabachnikoff, is transcribed and annotated by Giovanni Pinnati, has a French translation and introductory study by Matthias Duval. Cited usually as "Fol. A and B."
2. *Quadern d'anatomia*. Fogli della Royal Library di Windsor. (Christiana, J. Dybbald, 1911-1914. 4 volumes of 6 so far appeared, folio. Published with introduction, English and French translation by Ole C. L. Vangsten, A. Foschi and H. Hopstock. Cited "Quadern.")
3. Notes et dessins. Feuillet inédits, reproduits d'après les originaux à la Bibliothèque du château de Windsor. 12 volumes, folio. Paris, E. Rouveyre, 1901. This edition, usually cited as the "Rouveyre edition," contains facsimiles of the whole Windsor Codex but without transcription or translation.
4. *L'Anatomia di Leonardo da Vinci nella Biblioteca Ambrosiana di Milano*. 2 volumes, gr. fol. Milano, U. Hoepli, 1894-1904. Published by the Royal Academy dei Lincei, transcribed and annotated in Italian by Giovanni Pinnati.
5. Les manuscrits de Leonardo da Vinci. 6 volumes, folio. Paris, A. Quantin, 1881-1891. This edition contains the Mss. A; B and D; C; E and K; F and J; G; L and M of the Institut de France and the two Ashburnham Mss. (Ash 1 and 2) of the Bibliothèque Nationale at Paris. The transcriptions, French translation and annotation, as well as an extensive study and a subject index are by Charles Ravaut-Mollon, by whose name this edition is usually cited.

NOTE.—Most of Leonardo's anatomical and physiological legacy is contained in 1, 2, and 3 of the above editions. Of these, 1 and 2 duplicate the facsimiles in 3, providing them with translations; therefore, when 2 is once completed 3 will become obsolete, but not 1, 3 fact sometimes overlooked. The editions 4 and 5 contain but little anatomy, but rather physiology and physiological optics. There are, furthermore, four or five other facsimile editions of extant Leonardo Mss., but they contain hardly any anatomy.

The literature on Leonardo's anatomy has already reached considerable proportions. References to it are to be found under "da Vinci" in Vol. XX, second series, 1st degree of the Bibliothèque General Library, 1915. To Prof. Hoff's reviews of the *Quaderni*, which have appeared from 1911 to 1915 in the *Archiv für Anatomie*, etc., the author acknowledges his special indebtedness.

## Original Articles.

### HEMATOCELE OF THE TUNICA VAGINALIS, WITH THE REPORT OF AN UNUSUAL CASE.\*

By CHARLES M. WHITNEY, M.D., BOSTON,

*Professor of Genito-Urinary Diseases, Tufts College Medical School.*

HEMATOCELE signifies, from its derivation, a blood tumor and may occur in various parts of the body, but in genito-urinary practice, it indicates a collection of blood in the cavity of the tunica vaginalis, or in some pathologic, intra-serotal cyst.

According to the causes which produce it, this condition may be acute or chronic, for each type has its own peculiar, etiologic factors. An acute hematocele may be followed by a chronic one, but is not always, while one of the chronic type may be so from the start, and not preceded by an acute manifestation.

Strictly speaking an hematocele should mean an effusion of blood in the cavity of a normal tunica vaginalis, and when this occurs in other sacs, hydrocele, spermatocele and the like, it should be described as a hydrocele with blood or a spermatocele with blood, but it is more convenient to apply the term hematocele to all intra-serotal sacs which contain blood.

Clinically, therefore, the subject is divided into the primary form, where the blood effusion takes place in a normal tunica vaginalis, and the secondary, where the blood is mixed with the contents of other and pathologic sacs. This latter form is relatively the most frequently seen, and it may be well to consider it first and to review the causes which produce it.

First in frequency of this variety is the effusion of blood in a hydrocele.

A greater or less collection of fluid having taken place in the cavity of the tunica vaginalis, a sac is formed, the walls of which are distended in varying degrees, according to the amount of fluid contents. A blow or fall upon this distended sac meets with the increased resistance of the fluid, a rupture of the blood vessels of the walls of the tunica vaginalis occurs, and a varying quantity of blood is poured out and is mixed with the hydrocele fluid.

As a rule, there is extensive ecchymosis of the skin of the scrotum which is gradually absorbed. If the quantity of blood which escapes into the hydrocele is small, as it usually is, there may be no great increase in its size, but it pursues its normal increase as more fluid is secreted from its walls and it is only when it is tapped that we discover the presence of blood. The fluid is then of a very dark-brown color, sometimes black, and no clots are present, the sac collapsing com-

pletely after removal of its contents. A case which well illustrates this is the following:

CASE 1. A man of 77 had a hydrocele of 20 years' duration, which I had tapped at intervals of four to six months for 10 years. As he had moved into a distant place in the country I did not see him for 18 months and the sac had filled to a large size. When it was tapped, instead of the normal yellow of the hydrocele fluid, there was present a thin fluid of a black color, which was easily recognized as caused by the presence of blood. Upon questioning him as to any injury he had received in that region he recalled that 14 months before he had been riding in his farm wagon over a rough field when it ran over a stump. He was thrown up and fell back with great violence upon a hard wooden seat. A great deal of pain at once resulted and the tissues of the scrotum were extensively ecchymosed and swollen. This was gradually absorbed and the circumstance had passed from his mind.

This case was interesting not only from the slight effect such a severe blow had upon the course of the hydrocele but also because it shows how little power of absorption is present in the endothelial lining of the tunica vaginalis.

The black color of the fluid showed that it had been present for a long time and thus corresponded to the history given by the patient. A further interesting fact was that no clots were present as the sac was completely emptied through a small cannula. Many similar cases have been seen by the writer, but in no case was there so long an interval between an injury and the tapping of a sac containing unabsorbed blood. Another and very common cause of these secondary hematoceles is an injury to the walls of the tunica vaginalis by a trocar used in tapping a hydrocele. A leakage takes place into the cavity and the sac refills until in forty-eight hours it may be as large as before tapping. As a rule, a moderate ecchymosis occurs in the skin and fullness and pain are complained of. If a large amount of blood has been rapidly poured into the sac, clotting occurs and the fibrin is gradually separated from the clot and attaches itself to the walls, which become thickened and firm. Thus we have developed a chronic hematocele which is firm, non-elastic and not translucent to light, resembling a solid growth. As the hydrocele fluid re-forms, a tumor results, partly fluid and partly solid, and after tapping the hydrocele the fluid escapes, leaving behind the solid masses of organized blood clots. Such cases require operative relief.

Another result which is more favorable but less common is the cure of a hydrocele by the development of an hematocele within its cavity. A careful search of the literature of the subject has failed to find cases reported where this has occurred, yet that it does happen may be seen by the following cases:

CASE 2. A man of 40 consulted the writer 15 years ago for the treatment of a small hydrocele which was secondary to tuberculosis of the testis

\* Read at a meeting of the Staff of Mt. Sinai Hospital, Oct. 23, 1915.

and epididymis. Removal of the testis on the opposite side had been done five years before for tubercular disease. As the size of the sac caused him some inconvenience it was tapped, but in four or five months refilled, when it was again tapped. On his third visit, six months later, he was similarly treated but with quite different results. Within a few hours the scrotum rapidly swelled, the skin became ecchymotic and the cavity of the tunica vaginalis was filled to extreme distention. Rest in bed with ice bags soon caused an amelioration of the symptoms, the swelling slowly disappeared and the hydrocele did not return as usual nor has it since, for this patient has reported for examination within a month.

CASE 3. A man of 32 had a hydrocele which had been tapped twice a year for seven years, and for the last three years by the writer. After each tapping the sac was thoroughly emptied and no symptoms were noted. At the last operation the fluid was removed as usual but within a few hours the sac began to refill, the skin was ecchymosed and at the end of 48 hours it was as large as before. Palliative treatment was used, ice bags and rest in bed for a day, and later support of the scrotum by a large jockey strap. The swelling slowly decreased and the hydrocele has not returned.

Another similar case will be cited later which illustrates this as well as another fact in the etiology of the disease.

Two other similar cases have been observed. The probable explanation is that the blood clot acts as a foreign body and produces an irritation of the walls of the sac which obliterates it. We thus produce by accident the same result as we do when we insert catgut into the hydrocele or inject into it carbolic acid or tincture of iodine.

Another cause for this disease is the capillary oozing from the walls of an over-distended sac after tapping, just as it happens in the bladders of old men when too large an amount of residual urine is removed by catheterization.

I desire to add to the etiology of this disease one more cause which has not been mentioned before by any one, unless it has been overlooked in my search of the literature of this subject, and that is syphilis.

Every physician is familiar with the results of the arterial changes which take place from this disease elsewhere in the body, for example, hemiplegia, paraplegia, aneurysm and the like. There can be no doubt that a similar condition of arterial degeneration exists at times in the arterial coats of the blood vessels of the tunica vaginalis which permits minute ruptures and the slow or rapid effusion of blood into a hydrocele sac.

Very clearly is this shown by the following case:

CASE 4. J. B., 51 years of age, had syphilis 20 years prior to the present happening. For some years he had a hydrocele which had been tapped several times, the last two or three times being by myself. Considering that it needed tapping and feeling a little uncomfortable, he came in one day and I examined it and found that it was moderately distended, and prepared to tap it as usual but he

remembered that he had some important business to attend to and decided to wait. Three days later he returned and a great change had occurred, for in place of an elastic tumor he had one of stony hardness, resembling in all particulars a solid growth, and had it been the first time I had examined it I should have so diagnosed it. The fluid was easily removed through a cannula and showed a mixture of blood and hydrocele fluid. There was some reaction and the sac refilled rapidly but this absorbed and the hydrocele has never returned, showing the possibility of a cure by the development of this complication.

In this case there was absolutely no history of a blow or injury of any kind. Four other cases, which space does not permit me to relate, have suggested equally strongly the etiologic importance of syphilis. It must be remembered that not alone in hydrocele sacs may blood be found but also in spermatoceles, which are usually not in the tunica vaginalis at all but outside of it, being developed from embryonic organs, the paradidymis or organ of Giralde and the hydatid of Morgagni. A blow upon this collection of fluid or a trocar wound may cause a hematocele.

CASE 5. A patient with a very large spermatocele was referred to me by Dr. Chenery, and upon tapping showed only the characteristic milky fluid. A second tapping six months later resulted in rapid refilling, so rapid that in 24 hours it was two-thirds of its original size and the serotal tissues were swollen and ecchymosed. This subsided gradually and the case has not been seen since.

Among the rare causes for both primary and secondary hematoceles are hemophilia and scurvy.

The occurrence of the primary form of an hematocele is not common because a blow upon the scrotum is much more apt to cause an effusion of blood into the serotal tissues forming a hematoma, than to produce a collection of blood in the relatively small space normally present between the walls of the tunica vaginalis. The following case shows very clearly, however, that it may happen, that it may reach an enormous size and that, by the pressure upon the tissues covering it, it may cause great danger to life when neglected.

CASE 6. A man, 51 years of age, married, by occupation a baker, consulted me on Nov. 22, 1912, regarding a large tumor on the right side of the scrotum. Two months before his visit he had fallen from his wagon, across one of the shafts, striking the right side of the scrotum with great force. Immediate swelling and pain resulted and after the acute symptoms subsided there was a gradual increase in size. At the time of his visit a tumor as large as an adult head apparently occupied the whole of the scrotum. The penis could not be seen, but on the left of the swelling was an opening where the skin was apparently folded in and at the bottom of this the glans penis could be felt. The tumor was tense, moderately fluctuant and not translucent, and there was no pain on pressure or impulse on cough-

ing. This condition is well shown in the accompanying illustration, taken after it had again refilled.

The sac was punctured by a trocar which was followed by the escape of a fairly thick fluid containing a large amount of blood of rather bright color. It came slowly through the cannula and it required an hour to empty the sac partly. More than three quarts (105 ounces) of fluid were removed and a large soft mass of blood clots still remained in the sac. Many small clots were present in the fluid withdrawn. Immediate operation was advised and accepted, but for business reasons it was put off from time to time until Jan. 7, 1913. Meantime the sac refilled until at the time of operation it was larger than at the first visit. Due to the tension upon the walls of the sac and the scrotal tissues a slough, the size of a hand, formed at the lowest portion of the swelling, from beneath which a thin, bloody discharge oozed. A slight elevation of temperature (100 F.) appeared and sepsis was evidently imminent and his color and appearance was that of a sick man. Because of his obesity (nearly 300 pounds), his poor color and bad heart action, he was a poor other subject, and spinal anesthesia was decided upon and applied. The operation was performed by Dr. Arthur P. Janes, Dr. E. W. Cushing, consultant.

An incision was made high up in the groin and continued over the sac around and including the slough. The cord was first dissected and the tumor mass below was gradually loosened from its attachments and removed without entering its cavity. A considerable portion of the redundant skin and subcutaneous tissue was also removed. The incision was partly closed by sutures, leaving a large space below for drainage. Primary union was not expected nor obtained and the convalescence was slow but ended in complete recovery.

The pathologic examination of the mass removed was made by Dr. Timothy Leary at the Tufts College Medical School and was as follows:

Specimen consists of tunica vaginalis distended to form an enormous thick-walled sac, 23 x 13 x 10 cm. Along one surface of the sac can be traced the sper-

matic cord. Lying at end of cord and but slightly elevated above surface is a rounded mass 3.5 cm. in diameter. Section here shows what appears to be testicular tissue extending to a depth of 2 cm. Vessels of surface are dilated and injected.

On laying open, wall of sac is seen to vary in thickness from 4 mm. at base to 1.5 cm. at top. Sac is filled with clot and a clear jelly-like material. Along inner edge of wall can be seen delicate gray-white strands of tissue running into clot.

The skin received with specimen measures 17 x 8 cm., is thick, coarse, hypertrophied. In the subcutaneous tissue are seen three rounded masses, one at either end of skin and one in center measuring (a) 5.5 cm., (b) 4.5 cm., and (c) 2.5 cm. in diameter. On section, *a* and *c* consists of rather soft, red-brown tissue, *b* consists of a thick-walled sac filled with edematous gray-white tissue.

Mx. shows in wall a marked increase in fibrous connective tissue with a heavy infiltration with lymphoid cells. In places occur masses of old clot undergoing organization. The wall shows occasional small abscesses. The contents of sac consists of clot with masses of pus in places undergoing organization. Mx. through skin nodules show merely a chronic inflammatory picture.

*Diagnosis.*—Chronic and acute inflammatory.

The unusual features of this case are the rapid formation of an hematocoele containing more than three quarts of fluid, the rapid refilling of the sac, and the great danger from septic infection from the patient's neglect to have the operation done promptly.

The important point to the clinician in the pathology of this disease is the effect upon the testis when a large amount of blood rapidly escapes into the cavity of the tunica vaginalis and fills it with clots. The fibrin is separated and adheres to the walls in layers and the cavity itself is filled with a gelatinous material. The walls become thickened and from this and the internal pressure atrophy of the testis occurs, which indicates the necessity of early operative measures in cases of this type. The diagnosis is usually easily made in acute cases by the history of an injury, the ecchymosis of the scrotum if present, and by aspiration of the sac, which shows a blood-stained fluid.

Much greater difficulty in diagnosis is present in chronic cases or in the acute forms where the blood clots fill the sac.

We then have a firm, non-elastic swelling which does not transmit light, is not tender to pressure, and aspiration does not show the presence of fluid because the clotted blood will not escape through the needle. The diagnosis lies between benign or malignant growths, syphilitic orchitis, tuberculosis and certain forms of hernia, as well as hydrocele and extra-vaginal cysts.

The treatment of hematocoele depends upon the amount of blood present and whether it is a primary or secondary form.

In the small collections of blood which form in the cavity of the tunica vaginalis, rest and cold applications should be sufficient to cause absorption of the blood contents. Where a little blood is mixed with the contents of a hydrocele or spermatocele no treatment is required as it is usually not recognized until the fluid is later removed. But in those cases where the quantity of blood is large enough to clot quickly and fill the cavity into which it escapes with a solid mass of clots,

an early operation is necessary. The condition present in such cases is very well shown in the photograph of a specimen of hematocele from the Pathologic Museum of Tufts College Medical School. The cavity of the tunica vaginalis is filled to extreme distention with clots and in the walls may be seen white masses of cholesterol crystals.

An incision and removal of the clotted blood is usually enough for these primary cases but in those secondary to hydrocele the sac should be removed as in the ordinary operation for this disease. In very old cases with thick walls and involvement of the testis a castration may be indicated but should be avoided when possible.

In operating upon cases of apparently malignant disease of the testis the possibility of this condition being present should be kept in mind, and a small incision made into the growth may aid the diagnosis and treatment.

## A STATISTICAL STUDY OF THE MORTALITY FROM DIABETES MELLITUS IN BOSTON FROM 1895 TO 1913, WITH SPECIAL REFERENCE TO ITS OCCURRENCE AMONG JEWS.

By H. MORRISON, M.D., BOSTON.

THE testimony of observers, both in America and in Europe, goes to show that diabetes mellitus occurs more frequently among Jews than among their neighbors. With a view of getting data on this matter at first hand, I undertook a statistical study of the mortality of this disease from the death returns as recorded at the office of the City Registrar of Boston. This investigation covers a period of nineteen years,—1895 to 1913,—during which there were reported 1775 deaths due to diabetes mellitus. Of these, 127 were among Jews out of a total of 6936 deaths from all causes, and 1648 were among non-Jews out of a total of 222,532 deaths.

These figures show that the ratio of the number of deaths due to this disease to the total number of deaths from all causes is 0.018 among Jews and 0.007 among non-Jews. From further analysis I get this ratio to be 0.014 for those of German parentage, 0.013 for those of English parentage, 0.012 for those of American parentage, and 0.009 for those of Irish or Canadian parentage. In Boston, therefore, diabetes mellitus has been twice as frequent a cause of death among those of German, English or American descent as among their neighbors, and two and a half times as frequent among Jews.

### SIMILAR INVESTIGATIONS IN OTHER CITIES.

In a similar study in Frankfurt-a-M., Walbach<sup>1</sup> found that during the years 1872 to 1890 there had been 171 deaths from diabetes in that city; the proportion of deaths from this disease to the deaths from all causes was six times as great among Jews as among the other inhabitants. Auerbach<sup>2</sup> in an analysis of the demography of the Jews in Budapest, Hungary, found that of the 487 deaths reported as due to diabetes during 1902-7, 238, or more than half, occurred among Jews, though they constituted only 23.6% of the population; the rates were 5.9 deaths due to diabetes per 100,000 Catholics and 21.4 per 100,000 Jews. Namyu, Frerich, von Noorden and other specialists in diseases of metabolism also found that Jews supplied an extremely large quota of their patients, suffering from diabetes,—Frerich<sup>3</sup> 25%, and von Noorden<sup>4</sup> as high as 38.8%.

In New York City Stern<sup>5</sup> found the mortality from this disease among Jews in 1899 relatively more than double that among the non-Jews. Rudisch and Aronson<sup>6</sup> have investigated the morbidity of this disease in the New York Mt. Sinai Hospital and compared it with that in four non-Jewish Hospitals in that city; they came to the

conclusion that after making all allowances for the chances of error, diabetes mellitus is nearly three times as prevalent among Jews as among their neighbors.

#### THE MORTALITY FROM DIABETES MELLITUS IS STEADILY INCREASING.

There has been a general increase in the mortality of this disease both in this country and in Europe. According to the United States census the death rate from diabetes mellitus was 0.9 per 100,000 population in 1850; 1.1 in 1860; 2.1 in 1870; 2.8 in 1880; 5.5 in 1890; 9.3 in 1900; 14.9 in 1910. In Boston the death rate of this disease was 7.1 per 100,000 inhabitants in 1895; it rose steadily to 21.3 in 1913. In New York City it rose from 2.9 per 1000 total deaths in 1889 to 10 in 1910. In the same terms for Boston, it rose from 3.1 in 1895 to 13.3 in 1913. It is incorrect, however, to assume that this increase is accounted for by the increase in the Jewish population of these cities, as is done by Wilson<sup>7</sup> in the *Medical Record* of 1912, p. 662. He there traces two curves, one showing the increase in the death rate of diabetes in New York City as mentioned above, the other showing the increase in the Jewish population in that city. Because these two tracings are parallel in their upward direction this writer takes it for granted that the increased death rate from diabetes in New York is due to the increase in the Jewish population. The increased tendency to diabetes, however, has been general throughout all civilized communities, even where Jews do not form an appreciable element in the population. Certainly in Boston the increase of the Jewish population has not been the cause of the increased death rate from diabetes. An analysis of the death rate from diabetes per 1000 total deaths during the period under consideration, as indicated by the following curves, shows that it has not been appreciably affected by the death rate from dia-

betes among Jews, though this has been certainly relatively high.

#### NATIVITY.

The largest number of deaths from diabetes in Boston during the period investigated occurred among those of Irish parentage—656 out of a total of 1775—more than one-third. This, however, is not out of proportion, for the Irish are the predominant element in the population of Boston. The ratio of their number of deaths

from diabetes to their total number of deaths is 0.009, while that for the entire community is 0.007. The following table gives the nativity or nativity of the parents of those who had died from diabetes during the period investigated:

TABLE II.

Only in eleven instances was diabetes the cause of death in negroes; this is in accord with the general observation that diabetes is not common among the colored races. Among Jews who died from diabetes, the largest number occurred among those who had immigrated from Russia.

## AGE AND SEX.

The youngest case reported as having died from diabetes was that of a newly-born infant taken from a diabetic mother, who also succumbed. The oldest case was a woman of eighty-seven. The largest number of deaths from diabetes recorded was in persons of the seventh decade—60 to 70; the next largest was in the sixth decade. Only one-fifth of the deaths occurred in persons under forty. There was practically an equal number of deaths in children under ten and in persons over eighty.

Contrary to the general observation that diabetes occurs more frequently in the male than in the female sex, in this series there were 958 females, or 55% of the total, and 817 males, or 45% of the total. Above the age of twenty, also, there were more deaths from diabetes among women than among men,—916 to 760.

Total	33	66	110	144	286	403	525	234	32	

## DURATION OF THE DISEASE.

An analysis of the death returns investigated does not give one anywhere near a true estimate as to the probable duration of diabetes. Of the

1775 returns 567 do not give the duration at all, while 267 have the indefinite terms "years" and "months". Only a little more than half, 951, have the duration of the disease in definite terms. These show that the largest number of deaths from diabetes occurred in persons who had apparently had the disease one year or less. The longest duration recorded was in the case of one man, who had had it for thirty years.

## COMPLICATIONS.

The following analysis shows the frequency of some of the conditions associated with or complicating diabetes mellitus in the causation of death. Coma occurred in 362 cases; gangrene in 178; pneumonia and bronchitis in 101; tuberculosis in 80; acute infections, as influenza and erysipelas in 68; carbuncle and furunculosis in 36. Cardiac complications are mentioned in 126 cases; renal in 88; hepatic in 4; arterio-sclerosis, including apoplexy, in 94 cases. Neoplasm is spoken of in 22 cases; syphilis in 2; pregnancy in 3; acromegaly and exophthalmic goitre in one each. The pancreas is mentioned in 3 cases.

## OCCUPATION AS AN ETIOLOGICAL FACTOR.

Several observers point out the frequency of diabetes among professional men. In this series of 1775 deaths from the disease 1135 occurred in children, women, and men retired from active life. Of the other 640 deaths 233 were among men in mercantile pursuits, 326 among artisans, and 81 among professional men.

## IS THERE ANY RELATION BETWEEN THE MORTALITY FROM DIABETES AND THE SEASONS?

More of the deaths from diabetes occurred in the six months of cold weather than in the other months. Of the 1775 deaths studied, 1008 took place in the months of January, February, March, April, November and December, as

against 767 during May, June, July, August, September and October. I believe there is no significance in this difference beyond the fact that death rate is generally higher in the winter months.

#### SUMMARY AND CONCLUSIONS.

1. During the period of 1895 to 1913 there were in Boston 1775 deaths from diabetes mellitus out of a total of 229,468 deaths.

2. In Boston, as elsewhere, there has been a steady rise in the death rate from this disease; it was 7.1 per 100,000 inhabitants in 1895 and 21.3 in 1913, or 3.1 per 1000 total deaths in 1895, and 13.3 in 1913.

3. The death rate from diabetes has been relatively very high among the Jews of Boston. The ratio of the number of deaths due to this disease to the total number of deaths from all causes during the period investigated was 0.018 among Jews and 0.007 among non-Jews; so that death from diabetes mellitus occurred about two and a half times as frequently among Jews as among their neighbors. A similar analysis, however, shows that the death rate from diabetes was also very high among those of German, English, and American parentage, 0.014, 0.013, and 0.012 respectively, so that death from this disease occurred about two times as frequently among them as through the community in general.

4. The largest number of deaths from diabetes occurred among those of Irish parentage, 656 out of 1775, or more than one-third of the total. This death rate, however, was not out of proportion to their population. There were only eleven deaths from diabetes among negroes in Boston from 1895 to 1913.

5. This series of 1775 deaths from diabetes is made up of 958 females as against 817 males. This is contrary to the general observation that diabetes occurs more frequently in the male sex. The largest number of deaths occurred in persons of the seventh decade.

6. The duration of this disease cannot be estimated from this study, for nearly half the death returns either did not answer at all this question or gave it in the indefinite terms of "years" and "months". This is a point to be borne in mind in making out death certificates.

7. Why is the death rate from diabetes mellitus rising? Better and more thorough diagnostic methods may be a factor, but only a minor one. Diabetes mellitus keeps pace with the increasing complexity of civilization. It is more commonly found in large cities among individuals and races who are constantly under physical and nervous tension. As Kleen\* puts it: "With greater intellectual exertion, keener emotions, higher nervous development, more earnest struggle for existence, more urgent demands, a more intense culture we are bound to find more diabetes mellitus." It is particularly prevalent among Jews, not because of ethnic peculiarities,

but because a severe environment during many centuries has developed a nervous type easily thrown out of balance.

I wish to take this opportunity to thank Mr. E. W. McGlenen, Registrar of Boston, for his courtesy in allowing me to carry on this investigation in his department.

### THE TREATMENT OF CHRONIC DISEASE IS A PROBLEM OF APPLIED PHYSIOLOGY.\*

BY FRANCIS H. McCREDEN, M.D., S.B., BOSTON.

*Laboratory Director, Robert Brigham Hospital, Boston; Assistant Professor of Applied Therapeutics, Tufts Medical School.*

Pathological-anatomical-bacteriological investigations have contributed much to advance the treatment of acute infectious disease in the last half century, but they have done little to advance the treatment of chronic disease. Though the death rate has decreased by one-half in the last century, and the expectation of life has increased by a dozen years, the improvement is due to progress in the control of acute disease; while the death rate in the registration area of the United States has decreased steadily in the last generation—19.8 in 1880, 19.6 in 1890, 17.8 in 1900, 15.0 in 1910, 13.6 in 1914—the mean death rate for persons over forty years of age, those chiefly affected by chronic disease, has actually increased—3% between 1900 and 1910, and 21.2% between the years 1880 and 1910. Pathological-anatomical investigations have, indeed, tended to decrease rather than to increase optimism; no one who has made himself familiar by actual post-mortem examination with the terribly destructive changes found in the organs in many of the chronic diseases can believe that drugs will restore these organs to their normal conditions. This pessimistic attitude toward the possibilities of treatment in chronic disease is due to a wrong point of view concerning the purpose and principles of treatment: to the fact that too much

\*Part of an address read before the joint meeting of the Association of American Medical Colleges and the Federation of State Medical Boards, Chicago, Ill., Feb. 8, 1916.

emphasis is laid on the anatomy, and too little on the physiology of disease.

The more hopeful light in which the possibilities of treatment in chronic disease are seen when we fix the attention on physiology can be brought out by considering the purpose and methods of treatment.

The aim of treatment in acute diseases is complete removal of disease, or diseased material, or the cause of disease. The antitoxin treatment of diphtheria, and the removal of a diseased appendix are among the best examples. But even in the case of acute diseases like scarlet fever and measles, in which such direct radical treatment is not yet available, and in which the disease must be left to run its course, to be combated by the natural defences of the body itself, the result aimed at, in promoting conditions under which the body will act to best advantage, is also complete removal of all evidence of disease.

In chronic disease, though we often use the direct therapeutic methods of acute medicine, the most important part of the treatment usually has a different objective; it has to do, not with structure, but with function. An organ may be the seat of disease and yet, on account of the very great reserve powers of all the organs, functionally efficient. The normal heart, it has been calculated, can do six times the work ordinarily required of it; and the factor of safety of certain double organs, since one of the pair can be removed without danger to the patient, must be at least 100%. But with severe disease there comes a time when the affected organ cannot do the amount of work ordinarily required of it; the physician is then called in, not to make the organ anatomically perfect, but to restore equilibrium between the work required of the organ and the work which it can do; and though the diseased organ may never be made anatomically normal, it may be made functionally efficient, that is, competent to its tasks. When the heart, for example, becomes so badly affected that the amount of work it can do is less than the amount required, when compensation fails, the leaky valve or other anatomical change responsible for the condition cannot be removed or made whole. But the patient does not demand this; he wants the symptoms alleviated so that he will be more comfortable and better able to do his work; it is not *anatomical integrity* that the patient demands but *functional efficiency*.

Not only in chronic disease, but also in those specific infectious diseases in which direct treatment is not yet available,\* the treatment is directed toward improvement in the function of the various organs. The basis of the trouble in chronic disease is usually a disorder of some special organ or function—the heart, the kidney, the sugar metabolism, for example—and treatment is centered around improvement in the

efficiency of this organ or function; the same methods of treatment are applied in most of the acute infectious diseases, but they are not centered on improvement in the efficiency of any one organ or function.

Functional efficiency may be improved, equilibrium—though perhaps on a lower plane than the normal—between work required and working power may be brought about by two groups of methods: (1) methods which decrease the demands upon organs, (2) methods which stimulate organs to do better work; and therapeutics deals largely with questions of when and how to apply such methods. *Therapeutics is, therefore, in great part, a branch of applied physiology.*

Question may arise as to the correctness of the physiological point of view outlined here. It cannot be denied that the facts upon which the anatomical view of disease are based are as correct as the physiological facts; but facts alone, though they are the elements from which the truth is formed, do not make the truth; the truth has many aspects, and the important thing in determining the best aspect of a truth lies not alone in the correctness of the facts, but in the pragmatic value—in the Kantian sense—that the point of view which results from the selection of the facts and the distribution of emphasis among the facts has as a useful productive agent.\* With this criterion of usefulness as a guide, let us contrast, from the standpoint of therapeutics, the hopeful physiological aspect of disease with the anatomical aspect.

I have already referred to the pessimistic attitude toward the possibilities of treatment in chronic disease resulting from the pathological-anatomical viewpoint; even eminent practitioners, because of the difficulty of believing that treatment can influence the structural changes which the anatomical view brings into prominence, often show a tendency to consider the so-called chronic and incurable diseases as hopeless conditions having an inherent downward tendency. But most chronic diseases do not have a downward tendency; they result in a weakness of function, and if the functional activity of the patient is adapted to his functional capacity the *status quo* may not only be maintained, but often improved. It is a mistake to associate together the words "chronic" and "incurable." The dictionaries (Century, Webster) define "incurable" as "beyond the power and skill of medicine," and give "hopeless"—a term which implies that the physician is powerless—as a synonym. Though the term "incurable" may, possibly, be properly applied to those acute infectious diseases not susceptible of specific treatment, whose course it is "beyond the power and skill of medicine" to influence directly, it should not be used with reference to such conditions as heart disease, Bright's disease, diabetes, and many other chronic diseases; we may, indeed, be unable to influence the anatomical

\* Preventive treatment belongs largely outside the field of what is generally understood as therapeutics. Direct treatment—diphtheria antitoxin, appendectomy, quinine, salvarsan, etc.—is but yet a limited field.

\* Compare Goethe's dictum, "Was fruchtbar ist, allein ist wahr."

changes found in these diseases, the anatomical changes may be incurable; but looked at from the standpoint of physiology, the disease is not "incurable"; the course of the disease, the functional efficiency of the patient, is amenable to, often indeed, largely determined by treatment. A patient whose leg had been amputated would not be sent away with the statement that, since it is impossible for him to grow a new leg, nothing can be done for him; by the use of an artificial leg, and by refraining from certain activities, such a patient can become nearly as efficient as a normal man; the same attitude should be taken toward patients with incurable lesions of internal organs; these patients, too, can often be made functionally efficient.

All this bears directly on the question of the correctness of the physiological point of view. Surely this optimistic point of view is a more useful guide, has greater pragmatic value in therapeutics than the pessimistic anatomical point of view. *If usefulness, pragmatic value, are measures of the correctness of a scientific truth, the anatomical point of view is a wrong one from the standpoint of therapeutics and the physiological point of view is the correct one.*

## ACUTE ARTHRITIS EXPERIMENTALLY PRODUCED BY INTRAVENOUS INJECTION OF THE STAPHYLOCOCCUS PYOGENES.\*

BY EDGAR C. STEINHARTER, B.S., M.D.,  
CINCINNATI, OHIO,

*Junior Gynecologist to the Cincinnati General Hospital.*

[From the Pathologic Institute of the Cincinnati General Hospital.]

IN a previous paper,† I pointed out that the staphylococcus organism of shifting grades of virulence localized on intravenous inoculation in different structures of the body, and that within certain limits a selective localization of this micro-organism for special organs could be developed by cultivation of the organism in functioning tissue. I also showed that when the staphylococcus attained an affinity for a certain structure of the body, a fresh subculture of the organism obtained from a focus of infection was apt to possess properties leading to its localization in that tissue.

The following remarks have reference to the production of arthritis by intravenous injection of a staphylococcus. The strain used was the one employed in the gastric ulcer series. It was obtained by blood culture from a case of septicæmia in man. At first, following intravenous injection of the organism into the general circulation of rabbits, the joints of the animals

showed no gross pathological change except a very occasional slight hyperæmia of the periarticular tissues. However, cultures of the apparently negative joints very often yielded a pure growth of the staphylococcus. As negative joints in the early rabbits experimented upon appeared so regularly, examination for arthritis was gradually discontinued; but when rabbit No. 47, following upon an intravenous injection of a ten-day-old agar culture of the staphylococcus isolated from a stomach wall focus of rabbit No. 45, showed distinct lameness in the left hind leg, and at autopsy revealed an acute arthritis, routine examination for joint lesions was resumed.

The material used for injection was prepared by suspending an agar slant culture in about 10 c.c. of normal saline. The usual dose of such an emulsion was 1 c.c. for a rabbit and 3 c.c. for a dog.

In this series all but one animal (a dog) were rabbits. The following are a number of typical protocols of the animals injected after the staphylococcus had attained a sufficient virulence to cause acute arthritis.

Rabbit No. 47, wt. 900 grams, was injected intravenously with one cubic centimetre of saline emulsion made from a ten-day-old agar culture obtained from a stomach wall focus in rabbit No. 45. About 24 hours later, the animal showed lameness especially in the left hind leg, but otherwise seemed quite well. It was etherized and autopsied 36 hours after inoculation. The elbow joints show slight hyperæmia, joint fluid clear and apparently not increased in amount. Both knees are swollen and red. The redness in the right leg is limited to the joint, but in the left leg, it extends down to, and includes the ankle. Incision into the knee joints liberates a thick sanguinous fluid. The stomach, appendix and other organs are negative. Cultures from the joints on agar and in aseptic dextrose broth show a pure growth of the staphylococcus. Cultures of the heart's blood are negative.

Rabbit No. 48, wt. 1025 grams, was injected intravenously with 1 c.c. of the same emulsion used in rabbit No. 47. The next day the animal appeared lame, but otherwise seemed normal. On the second day after injection it was etherized and autopsied. The knees and elbow joints are red and swollen. The joint fluid is increased in amount, that of the elbow cloudy and of the knee purulent. Fresh smears of the fluid show leucocytes, red blood corpuscles and staphylococcus in pure culture. The appendix is very slightly injected and shows two small white areas, which from previous experience, are recognized as foci of the staphylococcus. There is one small abscess in the muscles of the abdominal wall. The kidneys appear slightly congested, otherwise normal. The heart and stomach are negative. Cultures on agar and aseptic dextrose broth yield a pure growth of the staphylococcus.

Rabbit No. 56, wt. 975 grams, was injected intravenously with 1 c.c. of an emulsion of a 20-hour-old agar growth obtained by culturing knee joint of rabbit No. 47. About 72 hours later, the animal appeared very sick, and therefore, etherized

\* Received for publication May 9, 1916.

† Experimental Production of Gastric Ulcer, BOSTON MEDICAL AND SURGICAL JOURNAL, May 11, 1916.

and autopsied. The knees are very much swollen and red. The joint fluid is increased in amount and semi-purulent. The other joints appear normal. The appendix is acutely inflamed. The distal half is turgid, diffusely hyperaemic and rigid. The proximal half shows little change from normal. The heart shows myocarditis. The kidneys, stomach, gall-bladder and skeletal muscles are negative. Cultures of the knee, heart's blood and appendix yield a pure staphylococcus growth.

Rabbit No. 57, half-grown, injected with 1 c.c. of emulsion of the strain used in No. 56. On the fourth day after inoculation, the animal appeared to be very sick. It died the same day and autopsy was made shortly after death. The knee joints are acutely inflamed. The joint fluid is increased in amount and cloudy. The elbows are injected but not appreciably swollen. The gall-bladder is distended and measures two by one-half inches. Its wall is oedematous and studded internally with small white nodules, that under the microscope, turn out to be colonies of staphylococci. The fluid contents of the gall-bladder is mucous-sanguinous and tinged a pale olive green. A fine yellow sediment is found in the dependent portion of the bladder. Fresh smears of the fluid show staphylococci. Stomach, heart and appendix are negative. The kidneys are finely granular and yield a pure culture of staphylococci. Cultures of gall-bladder are also pure growths of staphylococci.

Rabbit No. 63, wt. 1025 grams, injected intravenously with 1 c.c. of an emulsion of a 24-hour old agar slant culture of knee of rabbit No. 57. Animal died about 72 hours later. Left elbow is hemorrhagic. Joint fluid is increased and turbid. Other joints are apparently negative. In the muscles of the legs and abdominal wall are numerous small abscesses. Heart shows myocarditis and endocarditis. Kidneys show a few very small abscesses. Cultures of all the joints, heart and kidneys are positive for staphylococci.

Dog, female, wt. 11 kilos., was injected into femoral vein with 3 c.c. of an emulsion of a 24-hour old agar culture from knee of rabbit No. 56. The next day the animal seemed normal and ate about three pounds of meat. On the second day, after the injection, she began to look sick and moved about with little energy. On the third and fourth days, she would not eat and lay stretched out in her kennel. Her abdomen was tender, rigid and spastic on touch. The floor of the kennel was partly covered with recently coagulated blood. The animal was etherized and autopsied at the end of the fourth day, wt. 9 kilos. While being etherized, considerable dark unclotted blood was discharged by rectum. Knee joints show slight redness of periarticular tissue and cloudiness of joint fluid. Elbow joints negative. Stomach shows a few hemorrhagic erosions. The duodenum shows about two centimeters from the pyloric ring, a necrotic area measuring 6 x 7 mm. The centre of it is a bleeding point and apparently the chief source of blood found in the lower bowel. There are numerous small hemorrhagic erosions throughout the duodenum. The ileum, jejunum and large bowel, except for the presence of blood in the latter, are negative. The appendix shows the mucosa to be thickly studded with punctate hemorrhagic elevations. The kidneys are congested, the gall-bladder is negative. Cultures of the duodenal ulcer,

duodenal and gastric erosions and appendix, show a mixed growth of the staphylococcus and colon bacilli. Culture of the heart's blood shows a growth of staphylococcus in pure form.

#### RESULTS.

The results shown by the protocols indicate that the staphylococcus is apt to localize in the joints and to produce typical lesions of arthritis, if the strain is of proper virulence. The organism recovered from the arthritic lesions has a decided tendency to again localize in joints.

In some cases the arthritis was the only lesion found at autopsy, but in other cases it was associated with one or more other lesions, namely, duodenal ulcer, appendicitis, cholecystitis, myocarditis, pericarditis, endocarditis, nephritis, colitis and myositis. These other lesions will form the basis of future reports.

According to these experiments, it seems to be true that while the organism used (a staphylococcus) may show a predilection for a particular region of the body, it will not always produce a gross lesion at the expected point of attack. In order to produce a gross lesion, it is necessary either for the staphylococcus to be of a certain grade of virulence, or for the tissue in which it has lodged to be suitably altered for the growth and action of the organism. This principle demonstrated itself repeatedly in the course of experimental production of gastric ulcer, and again in experimental production of acute arthritis.

#### REMARKS.

The results of localization obtained in connection with studies of staphylococci are singularly suggestive of Rosenow's<sup>2</sup> results with streptococci. A comparison of the total results in the two series will be made at a future time when the data are more complete. In the meantime, it seems worth the saying that if these facts apply in the cases of streptococci and staphylococci, it would seem to be possible that they may apply to still other organisms, for so far as we can determine, the essential factor governing localization, is growth in the tissue. After an organism has grown in a certain environment, it tends in later generation to select that environment, or at least, to thrive best in that environment.

#### CONCLUSIONS.

It has been pointed out in a previous communication that the staphylococcus may be caused very regularly to localize in the stomach after intravenous inoculation.

It appears that the same organism may be caused to localize in joints and produce typical arthritis.

I wish to express my thanks to Drs. Paul G. Woolley and William B. Wherry for their interest and valuable assistance in connection with these studies.

## THE DIAGNOSTIC SIGNIFICANCE OF THE WASSERMANN REACTION.

THE Wassermann reaction for the diagnosis of syphilitic states has now been sufficiently long in use to justify for itself a definite place in the armamentarium of the profession. To neglect its use in suitable cases is to deprive one's self of the most important method in the determination of the presence or, so to say, the past presence of some form of manifestation of syphilis. The importance of being in position to say with some degree of certainty, either in the differentiation from many chronic eruptions or growths of doubtful origin, in congenital cases, with respect to the permissibility of marriage in persons exposed, in many of the parasyphilitic states, as well as in the numer-

ous phases of jurisprudence relating thereto, that syphilis is the causative factor, is obvious. Many of these pathologically obscure conditions may, of course, coexist. With due regard, however, to the important diagnostic value of the Wassermann reaction, its significance must not be overestimated. The reactions, whether positive or negative, must not be taken as absolute in determining the presence or in excluding the existence of syphilitic states.

In general, it can be said of this reaction, as of other serological or allied reactions, that positive results are merely evidentiary, and that negative results do not bar out the presence of conditions sought to be determined by the reactions. A number of conditions, particularly of tropical origin, give positive Wassermann reactions, and hence, where there has been a possibility of exposure to such diseases, they must be excluded before even very positive reactions are resolved in favor of syphilis. On the other hand, in syphilitic reactions, as perhaps nowhere else, the reaction can be innocently, but especially deliberately, masked by a patient in whose interest it may be to hide the presence of the disease. Alcohol, even when not enough is taken to intoxicate, mercury or antisiphilitic treatment of any kind, will act to mask or make negative an otherwise positive reaction.

Moreover, the technic of the reaction is so delicate that the differences between slightly positive reactions, neutral ones, or slightly negative ones are too little pronounced to serve for diagnosis. The many modifications of this reaction that have been evolved in the interest of greater definiteness of reaction, or greater simplicity of technic, all testify to this difficulty. And besides, the personal equation of the serologist enters very largely into the nature of the interpretation put on a particular reaction, especially when it is borderline in degree. Equally good men may interpret a reaction diametrically opposite. Syphilographers appreciate this. They are wont to submit specimens of the blood of the same patient to a number of serologists, and to accept the majority finding, or, if it is a matter of the degree of the reaction, they average the results obtained. Determinations are not made from doubtfully positive or doubtfully negative reactions. Even a very positive reaction should

receive at least one other test, and, if possible, by a different serologist. For most syphilographers a Wassermann reaction has little or no value unless given above the name of a trusted serologist—so much does the value of the reaction depend upon a faultless technique and careful interpretation. A positive Wassermann reaction, at least  $+4$ , is diagnostic when found in conjunction with suspicious symptoms of lues, characteristic sears, parasymphilitic manifestations or the like. While in clinical determinations for the purpose of instituting treatment lesser assurances may be taken, in medico-legal cases or in the establishment of the fact of a cure, perhaps for marriage, the complete extent of the Wassermann assurance must be demanded. If the reaction is deliberately masked or there is otherwise a lack of voluntary coöperation between subject and examiner, the reaction becomes accordingly of less value.

The use of the Wassermann reaction on a rather large scale, as among immigrants, has often been suggested. While undoubtedly a great many positive Wassermann reactions would be obtained, they would be relatively few, and even these would be negatived by the fact that the reaction may be an expression of the many conditions to which immigrants coming from so many places may be exposed. The detection of active syphilitic disease could be more easily accomplished by thorough physical examination. Latent, non-active, and therefore non-contagious syphilis is significant because of the likelihood of transmitting the disease to offspring, but the difficulty of technique, the cost, the uncertainty of results, the ease of masking reactions and the medico-legal questions which would arise would hardly justify its universal use, even to forestall the admission of these undesirable luetic strains. The energy used and the expenditures involved, if applied to more thorough mental and physical examinations, would be of far more value in the exclusion of the unfit.

Until serological examinations are rendered more certain in their meaning, the results must be accepted only when obtained by the most competent workers and with due regard and due allowances for the difficulties, the uncertainties and the personal equations involved.

## THE SOMATIC FACTOR IN MENTAL DEFICIENCY.

INVESTIGATIONS into the causes and into the nature of many forms of mental deficiency have brought out the fact that many of them are due not so much to inherent and intrinsic maldevelopment or deficiency of the brain substance, of hereditary origin, but more often to a great many extrinsic factors which operate to close up certain paths of ingress to the brain and to exclude the necessary stimuli from exerting their influence in its development. Often it serves merely to deprive the mind of such orientation as is required of the mentally competent; more often the lack of it actually retards brain development. As soon as such paths can be made patent mental development can go on as in the normal. The mental deficiency exhibited in those having various sensory or motor defects very well exemplifies this etiological factor. The correction of the sense defects, particularly, "cures" many of those apparently defective. But when these sensory or motor paths are permanently closed and the brain is permanently deprived of these sources of stimulation and fertilization, then the mind remains permanently underdeveloped to the extent of the deprivation. When the extent of these closed paths is not too great there may be no appreciable amount of mental deficiency, unless, perchance, some special knowledge or ability, in which some special paths would operate, is required. Moreover, there are a great many senses outside of the five special senses, the unspecial ones, the non-development of which cause deficiencies of a greater or lesser extent. This can be made to account for many grades of deficiency, usually partial in character, for which no palpable somatic cause can be found, and for which no hereditary taint can be discovered.

The fact, however, that so large a number of the mentally deficient show some tangible cause for their deficiency gives hope that soon most of them will be found of that nature, and that the application of proper corrective measures will help to reduce the number of the misfit. Where, on the other hand, the causes are discovered, but are not correctable, a search can be made for patent faculties, those developed on an intensive scale, and the individual in this way be made useful. The many so-called "savant

idiots" illustrate the possibilities in this direction.

The purely somatic conditions causing mental deficiency are increased indirectly by the mass of deficiencies caused by environmental and nutritional abuses. The anemic, nervous and undernourished children can often be made mentally efficient by proper remedial measures.

The somatic conditions which should logically exercise the greatest influence on mental efficiency, but which are so often overlooked, are the neurological ones. While spinal affections play a small part, except when they reach the higher centres in their upward path, all neurological conditions affecting the brain have a very marked influence on the mind. Whether it is an epileptic condition, an apoplectic stroke, traumatic injuries to the brain, brain growths or other sources of pressure, arterial degenerations and the like, they all show some degree of mental deterioration. Besides, there are a great many lesser neurological conditions of indefinite symptomatology and pathology which are accompanied by rather more definite mental deterioration. Indeed, wherever there are found these vague neurological symptoms accompanying mental deterioration a more thorough search must be made for profound brain changes. There is a tendency to consider these dual manifestations as psychoses, particularly as a late development of dementia precox, when in fact they are regressions in the degree of mental development. In the inherent mental deficiencies there is no mental organization at all because of some somatic change. Here the reverse condition obtains: there is no mental organization because of subsequently acquired somatic etiological factors.

In any event it is very important to differentiate these causes. In the young, where the deficiency is somatic but remediable, proper diagnoses will reclaim a great many. In later deteriorations of neurological origin they will be given proper treatment where possible, instead of considering them dementias of late development and prescribing only custodial care. The diagnosis of mental deficiency as such is fraught with a great deal of danger and often with a great deal of injustice. Causal relations must be searched for in mental conditions as in the physical.

## NOTIFICATION OF PREGNANCY.

SUCH a radical proposal as the one to make pregnancy notifiable will, of course, arouse a storm of protest, especially from those quarters whence comes opposition to all innovations. And yet on examining the idea judiciously we find that it has much to recommend it, the obvious advantages being the beneficial effect which the proper supervision of pregnancy might be expected to have among the more ignorant mothers and the possibility of combating the twin evils of abortion and infanticide.

Dr. S. G. Moore<sup>1</sup> has given the matter considerable attention in the course of the Milroy lectures this year. He calls attention to the marvelous work of Morel de Villiers in France, who accomplished a complete abolition of infant mortality in a small rural community for a ten-year period—1893-1903. This remarkable result was obtained only by the strictest supervision of the period from the recognition of pregnancy until the baby was several years old. One of the features of this system was the compulsory notification of pregnancy. This example has been followed by the borough of Huddersfield, in England, where Dr. Moore is health officer; so far as possible, that is, provisions have been made encouraging the voluntary notification of pregnancy and seeing that such cases are followed up and given every advantage at the disposal of the community to ensure healthy offspring.

As might have been anticipated, the suggestion, which has been made very much in earnest in England, that notification of pregnancy be made compulsory, has been discussed with some heat. Dr. J. W. Ballantyne sums up the arguments for and against rather concisely in the *British Medical Journal* for April 22. The points in favor of the scheme are the statistical studies of pregnancy thus made possible, with the consequent stimulus to study of that important physiological period and the probably resultant check to the frequency of abortions and attempts at them. Against the scheme are its intrusion upon domestic privacy, the difficulties of making an early diagnosis of pregnancy in some cases,—and early diagnosis would be very important, so many abortions being done in the third month or earlier,—and finally the fact that the results aimed for seem to be gradually becoming attained by the modern education of the public in

hygienic matters, more particularly in sexual hygiene. Ballantyne does not believe that the time is ripe for compulsory notification, but suggests that the profession encourage voluntary notification and make it their duty to see that when a case is thus reported the mother is aided in every way possible so that she may herself become an ardent supporter of the system.

<sup>1</sup>The Milroy Lectures, on Infantile Mortality and the Relative Practical Value of Measures Directed to Its Prevention, delivered before the Royal College of Physicians of London, by S. G. Moore, M.D., during March, 1916.

## CRIMINAL ABORTION AND THE WILL TO SURVIVE.

At one of the Boston theatres during the past week there has been displayed to the public, only adults being admitted, a moving picture aimed to impress the laity with some of the evils of criminal abortion. For the first, private performance invitations were issued to a number of clergymen, physicians, and teachers,—men and women. Everyone present was asked to express an opinion in writing; and upon the approval of a majority, the public production of the film was permitted by the censors.

There was in the picture nothing immoral, obscene, salacious or otherwise objectionable. On the contrary, without morbid exaggeration, as in the case of *Damaged Goods*, it presented vice as a

"monster of such hideous mien  
As to be dreaded needs but to be seen."

Unfortunately, it erred in suggesting that abortion and birth-control are practised chiefly by the fashionable and well-to-do, whereas in point of fact they are even commoner among the poor and middle classes. Indeed, this is their greatest evil. If they affected only the rich, they would be of relatively little biologic importance.

Nevertheless, it is probably true that "guilty creatures sitting at a play,"—of whatever class,—may be moved by it. Therefore, it would seem that any effect which this picture might produce should be good,—since it could hardly be evil,—both in the self-conviction and possible reform of the guilty and in the education of the innocent. Whether it will be likely to produce any appreciable or important effect may well be questioned. As a matter of fact,

the control of the evils of criminal abortion, either procured or self-induced, depends ultimately on the awakening of a personal race-consciousness and will for survival among individuals at large. Any educational measure, however, which may aid, even in small degree, towards securing this end in the lay community, is to be approved by the medical profession.

## ANNOUNCEMENT.

### HARVARD GRADUATE SCHOOL OF MEDICINE, COURSE IN MILITARY MEDICINE.

THE Harvard Graduate School announced a course of lectures on Military Medicine to be given during July, chiefly by Major Chamberlain, of the Medical Corps of the Army. Unfortunately it was found at the last moment that Major Chamberlain could not be spared from the Mexican border, but, as he had already sent his lectures to the School, we are able to go on with the course essentially as announced. The lectures will be given by instructors of the Medical School and others, who are familiar with the subjects assigned to them.

These lectures are given in the Administration Building of the Harvard Medical School, at 5 p.m. daily (except Saturdays and Sundays) during July. They are open to members of the profession without charge.

The School will not be able to repeat the course in August, as expected, but will offer similar instruction next fall.

H. D. ARNOLD, M.D.,  
Dean.

## MEDICAL NOTES.

NEW YORK POLIOMYELITIS EPIDEMIC.—The epidemic of poliomyelitis in Brooklyn, N. Y., which we noted in last week's issue of the JOURNAL, continues to spread and seems to be assuming rather serious proportions. On July 1 there had been already 379 cases and 59 deaths; 23 more deaths occurred on July 1, 2 and 3. The New York Health Department is taking active measures to combat the disease and has issued frequent bulletins on the subject. The death rate of this epidemic is relatively high and has been computed as at least 20%, which is four times as great as the death rate during the extensive epidemic of 1907. At

a conference of Brooklyn physicians, held in Polhemus Memorial Hall under the joint auspices of the Department of Health and the special poliomyelitis committee, Dr. Simon Flexner presented a statement summarizing our present knowledge of the disease and the modes of its transmission and prophylaxis. On July 3 the Health Department reported 67 new cases. The Department has begun the distribution of 500,000 warning leaflets based on Dr. Flexner's statements. The Department has also postponed the holding of free open-air moving picture shows which it had been proposed to give during July, and has notified all motion picture theatres in the city not to admit children under sixteen years of age after July 5. On this date the total of reported cases was 702 and of deaths 138 since June 26. The Mayor has ordered a special bond issue of \$80,000 to provide funds for combating the epidemic. Great effort is being made to prevent the exportation of the infection to other cities, but several cases have already developed on Long Island and six at Hudson, N. Y.

**THE AMERICAN POSTURE LEAGUE.**—A joint meeting of the American Posture League and the American School Hygiene Association was held on July 5, in Teachers College, Columbia University, New York, N. Y. Papers were read by Dr. Eliza M. Mosher, Dr. William H. Burnham, Dr. Henry Ling Taylor and others.

**DENTISTRY IN THE FRENCH ARMY.**—In recognition of the importance of well-kept teeth to the soldiers in the French army, over one thousand dentists are employed in the medical corps, five hundred in the trenches and the rest in interior hospitals. Not only are their services demanded in keeping the teeth of the soldiers in good condition, but the large proportion of face injuries has required their most expert surgical skill in repairing and reconstructing damaged jaws and mouths.

**HONORARY DEGREES FOR PHYSICIANS.**—In a recent issue of the JOURNAL we noted the award of several honorary degrees to physicians at American university commencements. The following further awards have also been made: Colby University awarded the honorary degree of A.M. to Dr. James Frederick Hill of Waterville, Me. The University of Chicago awarded the honorary degree of LL.D. to Dr. William H. Welch, professor of pathology at Johns Hopkins University. The University of Vermont awarded the honorary degree of Sc.D. to Dr. Fred H. Albee of New York, and the University of Wisconsin awarded the same degree to Dr. Ludwig Hektoen, director of the Chicago Memorial Institute for Infectious Diseases.

**A GENEROUS MEDICAL GIFT.**—It is announced that Dr. Kenneth Doves of New York has re-

cently given the sum of \$95,000 to the Johns Hopkins Hospital to be devoted to the investigation of tuberculosis and to the training of physicians and students in the recognition of the disease and the management and care of patients.

**PREVALENCE OF MALARIA, MENINGITIS, PELLAGRA, POLIOMYELITIS, SMALLPOX AND TYPHOID.**—The weekly reports of the United States Public Health Service for June 23 and 30, 1916, state that during the month of May in this year there were reported eleven cases of cerebrospinal meningitis in Ohio, twelve in Massachusetts and thirteen in Wisconsin. In Mississippi there were 9,485 cases of malaria, 1,168 of pellagra, 148 of smallpox, 35 of poliomyelitis and 399 of typhoid. There were 87 cases of typhoid in Maryland and 75 in Massachusetts. Virginia reported 807 cases of malaria, 79 of pellagra, 28 of poliomyelitis, 107 of smallpox and 155 of typhoid. In Wisconsin there were 89 cases of smallpox and 41 of typhoid.

#### EUROPEAN WAR NOTES.

**BENEFACCTIONS OF THE ROCKEFELLER FOUNDATION.**—The war relief commission of the Rockefeller Foundation, has recently issued a report showing that during the six months ended June 30, 1916, it appropriated more than \$3,000,000, and has already expended over two-thirds of the appropriation.

"Of the total of \$2,159,985 expended during the six months, by far the largest amount was devoted to Belgium, \$1,290,292 having gone for the relief in that country or among Belgians in other countries. Armenian and Syrian relief was next with \$360,000, and Serbian relief third with \$148,894. An appropriation of \$1,000,000 for relief in Poland, Serbia, Montenegro and Albania is yet to be expended.

"For relief work in and about Constantinople, \$35,000 was expended, while \$55,000 was devoted to the surgical laboratory at Compiègne, founded by the Rockefeller Institute for Medical Research and which is under the direction of Dr. Alexis Carrel.

"Other appropriations made by the Foundation, exclusive of war measures, include: American Academy, Rome, \$10,000; Bureau of Municipal Research, for Studies in the Administration of the Government of the State of New York, \$10,000; International Health Board, \$75,000; general education boards, \$250,000; for establishment and maintenance of school of hygiene and public health at Johns Hopkins University, \$267,000."

**FEVERS OF SERBIA.**—A recent study of fevers other than typhus abounding in Serbia reveals a condition in that section of Europe which is analogous to conditions in the Eastern Orient.

"In the valleys of the Save and the Danube there is a predominance of malarial maladies, the most common of which are the tertiary and double tertiary forms. Related fevers are recurrent, intermittent, oscillatory and some of very short duration. Many feverish states were found which depend upon intestinal intoxications, where there may be demonstrated not only the *B. coli* and types A and B of the paratyphoid organism, but bacteria ordinarily saprophytic, which take on infectious forms. *B. gärtneri* is one of the most common in the intoxications of alimentary origin in Serbia. There is here a great assemblage of fevers, which include Malta and Kala-Azar, and with these septicemic fevers produced by parasites which evolve in the mediums of the blood. Then again there are dysenteries and certain choliform diarrheas which seem to be produced by a vibriion peculiar to these lands."

**WAR RELIEF FUNDS.**—On July 8 the totals of the principal New England relief funds for the European War reached the following amounts:

Belgian Fund .....	\$133,407.15
French Wounded Fund .....	93,664.71
Army Huts Fund .....	66,190.60
British Imperial Fund .....	60,420.10
Armenian Fund .....	53,050.86
Polish Fund .....	38,915.37
Surgical Dressings Fund .....	37,213.87
Facial Hospital Fund .....	22,925.55
Italian Fund .....	20,260.04

#### MEXICAN NOTES.

**SCARCITY OF DRUGS IN THE UNITED STATES NAVY.**—Report from Washington on June 27 states that on account of the Mexican situation, request has been made of Congress for an urgent deficiency appropriation of \$55,000 to make up the scarcity of drugs in the Navy due to the present high price of medical supplies on account of the European War. One of the chief drugs, of which a large supply is required in the Navy in case of actual service, is quinine.

"The advance in the price of quinine has been irregular, ranging from 28 cents or 30 cents an ounce to \$4.00 an ounce, the highest price paid by the Government. The Navy is now purchasing it at \$1.60 or \$1.75, according to the way it can be picked up. At one time when the Government was in urgent need of quinine, dealers offered to sell a ton at \$4.00 an ounce, but this was too steep a price and the offer was rejected. This bid came from Amsterdam by cable and the purchase of a ton of quinine at this price would have cost in the neighborhood of \$125,000."

**MEDICAL TRAINING CAMPS AT PLATTSBURG.**—Report from New York on July 4 states that two training camps for medical men will be

held at Plattsburg for two weeks each, beginning on July 12 and 24, respectively. These camps will be opened to properly qualified physicians and surgeons, who will receive special courses in camp sanitation, military hygiene and first aid.

**BOSTON HOSPITAL UNITS.**—In last week's issue of the JOURNAL we noted the organization by the American Red Cross of a series of thirteen base hospital units in preparation for actual service in the event of war with Mexico, should need require. The three Boston units are based respectively on the staffs of the Massachusetts General Hospital, the Boston City Hospital and the Harvard Medical School. Each unit is to consist of 196 persons, comprising nine surgeons, seven physicians, three laboratory experts, two dentists, fifty nurses, twenty-five nurses' aids, one chaplain, with the necessary orderlies, ambulance drivers, cooks, waiters and clerks. The following is the medical personnel of the three Boston units as thus far constituted:

**Boston City Hospital.**—Dr. John J. Dowling, director; Dr. Edward H. Nichols, senior surgical officer; Dr. Joshua C. Hubbard, Dr. Walter C. Howe, Dr. Halsey B. Loder, Dr. Arthur R. Kimpton, Dr. Robert C. Cochrane, Dr. Irving J. Walker, surgical officers; Dr. Allen Greenwood, ophthalmologist; Dr. Calvin B. Faunce, otologist and laryngologist; Dr. Ariel W. George, x-ray; Dr. John J. Thomas, Dr. William H. Robey, Jr., senior medical officers; Dr. Francis W. Palfrey, Dr. Cadis Phipps, Dr. W. Richard Ohler, Dr. Albert A. Hornor, medical officers; Dr. Edgar M. Medlar, bacteriologist; Dr. Leroy U. Gardner, pathologist; Dr. Edmund W. Wilson, adjutant; Dr. William F. Dolan, quartermaster; and Miss Emma Nichols, chief nurse.

**Massachusetts General Hospital.**—Director, Dr. Frederic A. Washburn; adjutant, Dr. Byam Hollings; quartermaster, Dr. Eustace I. Fiske; assistant director, surgical section, Dr. Lincoln Davis; assistant director, medical section, Dr. Richard C. Cabot; assistant director, laboratory section, Dr. J. Homer Wright; surgeons, Drs. Zabdiel B. Adams (orthopedist), Beth Vincent, William J. Mixer, Ralph A. Hatch (oculist), Elliott C. Cutler, Arthur W. Allen, George A. Leland, Jr.; physicians, Drs. James H. Means, Andrew W. Sellards, George Clymer (neurologist), Paul D. White, Wade S. Wright; bacteriologist, Dr. Roger Kinnicutt; roentgenologist, Dr. Walter J. Dodd; dentists, Drs. Leroy M. S. Miner and Charles W. Ringer; chief nurse, Miss Sara E. Parsons.

**Harvard Medical School.**—Director, Dr. Harvey Cushing; assistant directors, Dr. Richard P. Strong, laboratory section; Dr. Roger I. Lee, medical section; Dr. David Cheever, surgical section; Dr. William H. Potter, dental section; adjutant, Dr. Louis H. Burlingham; surgeons,

Dr. George S. Derby (ophthalmology). Dr. Robert B. Osgood (orthopedics). Dr. Walter M. Boothby, Dr. Edward B. Towne, Dr. Frank R. Ober, Dr. Gilbert Horax, Dr. Samuel C. Harvey, Dr. Harris H. Vail (John Harvard Fellow, 1916), Dr. Thomas R. Goethals (John Harvard Fellow, 1916); physicians, Dr. Reginald Fitz, Dr. George C. Shattuck, Dr. George P. Denny, Dr. George R. Minot, Dr. Henry Lyman; dentist, Dr. Roger B. Taft; bacteriologist, Dr. James L. Stoddard; roentgenologist, Dr. Percy Brown; chief nurse, Miss Carrie M. Hall.

#### BOSTON AND NEW ENGLAND.

**THE WEEK'S DEATH RATE IN BOSTON.**—During the week ending July 8, 1916, there were 215 deaths reported, with a rate of 14.74 per 1000 population, as compared with 183 and a rate of 12.75 for the corresponding week of last year. There were 32 deaths under one year, as compared with 26 last year, and 57 deaths over 60 years of age, against 55 last year.

During the week the number of cases of principal reportable diseases were: Diphtheria, 45; scarlet fever, 14; measles, 202; whooping cough, 15; typhoid fever, 2; tuberculosis, 59.

Included in the above were the following cases of non-residents: Diphtheria, 7; scarlet fever, 5; measles, 1; tuberculosis, 5.

Total deaths from these diseases were: Diphtheria, 4; tuberculosis, 17; measles, 5.

**A NEW OPPORTUNITY: FELLOWSHIPS IN DISTRICT WORK.**—The Harvard Medical School has established four fellowships to be awarded to graduates in medicine, to be known as the Boston Dispensary fellowships. Applicants must have graduated from a medical school of good standing and must have had a hospital internship or its equivalent. Appointments will be made after consideration of applicants jointly by the authorities of the Harvard Medical School and of the Boston Dispensary.

The Boston Dispensary has for 120 years provided medical service to the sick poor in their homes throughout the city, the municipality not affording this sort of service. Under the fellowship arrangement, a portion (for the present not more than five) of the district men will be on fellowship appointment. Negotiations are pending between the Boston Dispensary and the Tufts Medical School with a view of making some similar arrangement for a fellow next year.

The duties of the fellows will be to give a portion of their time to clinical work in the district service of the Boston Dispensary, treating the sick in their homes; and a portion of their time to such study, teaching, laboratory, research or clinical work as may be assigned by the Medical School. The stipend of a fellowship will be \$500 when the physician gives part time, or \$750 when the physician devotes his entire time to

the district work and to the Medical School. A physician desiring to pursue post-graduate study or a course in public health work, for instance, might be enabled through such a fellowship to complete a course in one or two years while receiving at the same time valuable experience.

Application for these fellowships should be made to the Dean of the Harvard Medical School, Longwood Avenue, Boston, Mass.; or to the Director of the Boston Dispensary, 25 Bennet Street, Boston.

#### HARVARD MEDICAL ALUMNI ASSOCIATION.

The annual meeting of the Harvard Medical Alumni Association was held in Harvard Hall, Cambridge, Mass., on June 22, about 150 members being present. The following officers were elected for the ensuing year: President, Dr. Frederick C. Shattuck; secretary, Dr. Arthur B. Emmons, 2d; treasurer, Dr. James B. Ayer. Dr. Francis M. Rackemann, Dr. William W. Howell and Dr. Charles D. Eastman were elected councilors for a term of four years, and Dr. Elliott P. Joslin, councilor for the term of two years in succession to the late Dr. Silas A. Houghton.

**NEW ENGLAND DEACONESS HOSPITAL.**—The new private room annex of the New England Deaconess Hospital at Concord, Mass., the gift of an anonymous donor, was open for public inspection on July 1. The building, completed and furnished at a cost of \$20,000, contains eight private rooms, each with a sun porch and balcony, with nurses' quarters on the second floor.

#### WINCHESTER HOSPITAL TRAINING SCHOOL.

The annual graduation exercises of the Winchester Hospital Training School were held at Winchester, Mass., on June 23. The principal address was by Dr. DeWitt G. Wilcox of Boston. The president of the Winchester Visiting Nurse Association awarded diplomas to a class of three pupil candidates.

#### BROCKTON DEPARTMENT OF PUBLIC HEALTH.

—The thirty-fourth annual report of the Department of Public Health of Brockton, Mass., shows a steadily decreasing death rate and infant mortality rate. The death rate is the lowest since 1890, and the infant mortality rate the lowest since 1896. The birth rate was 23.9 per 1000. The six leading causes of death for the past five years in this city are, in order of their numbers, diseases of the heart and arteries, pneumonia, congenital debility, diseases of the brain and spinal cord, cancer and tuberculosis. Brockton maintains an unusually low infant mortality rate, averaging 2.8 per thousand inhabitants as compared with 3.7 for Massachusetts as a whole. Credit for this is given to the careful inspection of milk and the attention

that is paid to the sanitary conditions of the city. Two baby milk stations were conducted during June, July, August and September, 1915. One station is situated on the east side of the city where the population is largely Jewish and Italian, the other is in the northern section of the city, among the Lithuanian people. A total of 196 babies came under supervision, of which number 98 were brought to the milk station clinics. No deaths from diarrhoeal diseases occurred among these 196 babies.

### Miscellany.

#### RED CROSS APPEAL AND INSTRUCTIONS.

##### AN APPEAL TO THE AMERICAN PEOPLE.

WITH the calling of many thousand men into military service, new and heavy responsibilities fall upon the Red Cross, in its relation to the army and navy on the one hand, and to the people of the United States on the other. At present these responsibilities are, first, to provide assistance to the medical services of the armed forces of the government, by the organization of base hospitals, ambulance columns and other units for the care of our sick and wounded; second, to purchase, collect, forward and distribute supplies for our soldiers in field, camp and hospital; third, to help soldiers' families left destitute and not provided for by other agencies.

For the necessary means to discharge this patriotic service, the Red Cross, in accordance with its custom, turns to the public, whose sympathy and generosity it has learned implicitly to trust. Upon the response to this appeal must depend the adequacy with which the Red Cross will be enabled to help our sick and wounded soldiers, to soften the harshness of field service, and to meet urgent needs among dependents at home.

In anticipation of such a grave emergency as this, the Red Cross has been building up an organization competent to meet the obligations of its national charter and to make effective the generosity of a patriotic people.

Contributions may be sent to the treasurer of the local chapter, or checks may be made payable to the American Red Cross, and sent to national headquarters in Washington.

WILLIAM H. TAFT  
*Chairman, Central Committee,  
American Red Cross.*

##### INSTRUCTIONS TO RED CROSS CHAPTERS.

In accordance with the obligations of its National Charter and in keeping with the recognized purposes of Red Cross societies of all countries, the American Red Cross will parti-

cipate in the care of destitute families of soldiers and sailors called into military service. It is neither the intention nor the desire of the Red Cross, however, to monopolize this work. On the contrary the Red Cross hopes that through the patriotic generosity of employers, and possibly through governmental action, the chief part of this problem may be solved. With private agencies which enter this field the Red Cross desires to maintain relations of close co-operation to the end that the work may be done with efficiency and without confusion.

In its nature this relief work is local in character. It should never lose its spirit of neighborly sympathy and responsibility. For this reason the Red Cross will give its assistance through its Chapter and such other local organizations as it may authorize and will expect that the money and supplies necessary will be contributed by the communities in which the work is done.

##### DUTIES OF RED CROSS CHAPTERS.

In the instructions to Chapters dated June 22d, attention was called to the importance of dividing the work of each Chapter into a Section for Military Relief and a Section for Civilian Relief. The collection, purchase, warehousing, packing and forwarding of supplies to the soldiers and sailors is within the duty of the Chapter Section on Military Relief.

All work pertaining to the relief of destitute families of soldiers and sailors falls within the duty of the Section for Civilian Relief. The following instructions are for the guidance of Chapters in the conduct of relief operations in behalf of destitute families.

##### COLLECTION OF INFORMATION.

In order that the work of relief may be intelligently conducted and with justice to all, a carefully written record is necessary. This record should contain the facts on which the action of the Chapter is based in the case of each family. It should contain the name of the family, number and ages of children, a summary of the family's own resources and a statement showing whether help is also being received from other sources, and if so, how much. This information should be retained until the work growing out of the Mexican disturbance is completed, as it will be needed for reference from time to time and will serve as a basis for a report when the work is finished.

##### DISTRIBUTION OF RELIEF.

Avoid haphazard, spasmodic and irregular methods of administering relief. This duty should be entrusted to a strong, careful, unexcitable committee, and all distribution should be directed and controlled by that committee. It is desirable that the collection of information on which relief is given should also be under

the direction of this committee. A simple record should be kept of all relief given out and to whom given. At the beginning this record may seem unimportant, but as time passes it will be found indispensable if effective and satisfactory work is to be done. It will also be found of value in answer to criticism which is certain to arise.

#### SHALL RELIEF BE IN THE FORM OF CASH OR SUPPLIES?

No iron-clad rule should be laid down as an answer to this question. In general it may be said that money goes farther if it is expended by the committee in buying relief supplies in large quantities, at such discounts as generous merchants will allow. Also many contributions to the Chapter will be in the form of supplies instead of cash.

On the other hand it is probable that the recipients of the help in a majority of instances will be persons who are accustomed to buying for their households and know how to buy with economy. With cash they can buy such things as their families ordinarily use and prefer. The organization for giving relief in money is simpler and less cumbersome than that necessary for distributing supplies.

#### RAISING AND EXPENDING FUNDS.

For the purpose of maintaining the work of relief herein described Chapters of the Red Cross are hereby authorized to solicit contributions of money and supplies from the public, within their respective jurisdictions, and to expend or distribute such supplies and funds under proper safeguards. It is of the utmost importance that an accurate account shall be kept of all money received and all expended. Receipts must be taken for all money paid out, and no money should be paid out except on the approval of a Chapter officer or committee, vested by the Chapter with power to authorize expenditures. These financial accounts should be so complete and accurate that when they are audited later they will show the source of every dollar received and the place where every dollar went. The keeping of the books should be placed in the hands of experienced bookkeepers.

#### TACT AND FAIRNESS NECESSARY

Tact and absolute fairness are essential in the work of the Red Cross. It is to be remembered at all times that the families for whose welfare this work is carried on are independent and self-respecting and are objects of our solicitude solely because their natural supporters have been called into the service of the country to protect the lives and property of our fellow citizens. There is no shadow or taint of charity, in the offensive use of that word, in the work which the Red Cross is doing; it is in fact an attempt to fulfill a sacred obligation which

we owe to the men who are in the ranks for the protection of us all.

ERNEST P. BICKNELL,

Approved: *Director General,*  
ARTHUR MURRAY, *Civilian Relief,*  
*Acting Chairman,*  
*Central Committee.*

The following statement was issued on July 5 by Major General Arthur Murray, U. S. A., Acting Chairman of the Central Committee of the American Red Cross:

"Supplementary instructions for the collecting of military relief supplies as a result of the concentration of American troops on our Mexican border, just issued by the American Red Cross to its chapters and auxiliaries, name six intermediate depots in railroad centres of the United States where supplies should be sent by them to be assorted and classified, and three distributing depots from which final distribution of supplies will be made to the troops at the front. With two exceptions, Cincinnati and Denver, the exact addresses of the intermediate depots are given below. The points selected and the districts embraced are as follows:

"*New York District*, Red Cross Supply Depot, Bush Terminal No. 19, 39th Street and Second Avenue, South Brooklyn, N. Y.—Includes all New England and the Eastern part of New York State.

"*Cincinnati District*, headquarters in Cincinnati, O.—Includes Pennsylvania, the Western part of New York State, New Jersey, Delaware, Maryland, West Virginia, Ohio and Indiana.

"*Chicago District*, headquarters Red Cross Supply Depot, clearing Argo District, Chicago, Ill.—Includes Minnesota, Wisconsin, Michigan, and Northern Illinois.

"*Kansas City District*, Red Cross Supply Depot, care Montgomery, Ward & Co., Kansas City, Mo.—Includes North and South Dakota, Nebraska, Iowa, Northern Missouri, and North-eastern Kansas.

"*Denver District*, headquarters in Denver, Colo.—Includes Montana, Idaho, Wyoming, Utah, and Northern Colorado.

"*San Francisco District*, headquarters Red Cross Supply Depot, care Mr. A. B. C. Dohrmann, San Francisco, Cal.—Includes Washington, Oregon, Nevada, and Northern California."

The headquarters of the following additional three districts are designated "distributing depots":

"*Douglas, Ariz.*, headquarters Red Cross Supply Depot, care Mayor W. H. Adamson.—For all of Arizona and the southern part of California (Los Angeles).

"*El Paso, Tex.*, Red Cross Supply Depot, 516 San Francisco Street, El Paso, Tex.—For all supplies from intermediate depots at Kansas City, Denver, San Francisco, and from all territory west of Kansas not otherwise embraced.

"San Antonio, Tex., District, headquarters Red Cross", apply Depot, Avenue E and Fourth Street, San Antonio, Tex.—For all supplies from intermediate depots at New York, Cincinnati, Chicago, and from all southern states situated to the east of a north and south line through the western boundary of Kansas.

"Each depot will be under the charge of a manager who will have general supervision over the receipt, storage, and shipment of the supplies, and, in the case of distributing depots, of their final disposition. Instructions for the shipment of supplies to, and operation of, these depots have been prescribed at length—those relating to shipment of supplies may be obtained on application to Chapters.

"These intermediate and distributing depots having been established by the Red Cross for the purpose of facilitating the distribution of supplies from all parts of the country to our soldiers and sailors, the Red Cross would be pleased to have all patriotic American citizens and associations desiring to give aid and comfort to them make use of the facilities thus afforded by its system of depots for the shipment and distribution of supplies on the Mexican border.

ARTHUR MURRAY,  
Major General, U. S. A.,  
Acting Chairman, Central Committee,  
American Red Cross."

## Correspondence.

### A QUESTION OF MEDICAL ETHICS.

WAUKESHA, WIS., July 1, 1916.

Mr. Editor: For many years now the profession of medicine has been purging itself of poor medical schools. We have been trying to standardize the schools so as to eliminate the poor ones, to standardize hospitals and, in general, raise the level of medical education and through education the level of practice. The results of all this work are known to all the press and the public.

Physicians do not often go into print themselves but many give their time freely to interviewers who are better qualified to write their material up and who are given a wider hearing.

Recognizing as we have the tremendous inferiority of many happily defunct schools of medicine or diploma factories it is a sore in our side that the product of these schools, thousands in number, have to a greater or less extent obtained the confidence of the public and worse yet are virtually protected and shielded by the profession itself. Many of them are totally incompetent, and many are actuated by no desire to help humanity. Yet it is insisted upon by our code of ethics that nothing damaging to the profession should be allowed to get to the public ear. Criticisms should be made only in medical publications. There is no profession which holds its code of ethics so jealously. We are always suspicious of people who parade their virtue. They are more than likely to be assuming a virtue if they have it not.

It seems to me that we are decidedly at fault and that it is a false sense of loyalty that causes this

state of affairs, and the public has a perfect right to call us inconsistent and insincere.

Isn't our duty to the public as great or even greater than to the unit practitioner? Is it always necessary for the consultant to leave the impression with the family that the general practitioner is doing exactly the right thing? Even if no harm results from his ignorance, is it right to leave the impression that he is a proper guardian of the health of that family? Should we always shield the practitioner who never ought to have left the plow? Is the public expected to discriminate in matters medical? You can claim that tact will obviate all difficulties between consultant, practitioner and family, but it won't. It can't make a good practitioner out of a man who never made a physical examination.

In the first place we are all too afraid of admitting our mistakes and too afraid of telling other people theirs. More frequent consultations among physicians, group action, frank correction of mistakes and admission of error would in a short time benefit people and physicians both and would lead to a better understanding and ability to cooperate, which is lacking at present.

Our loyalty to false standards of loyalty creates between the profession and the public a legitimate atmosphere of suspicion, and in the profession it creates insincerity and lack of frankness. Our reluctance to admit our faults to the public and our mistakes among ourselves leads to outbursts of criticism when such an article as Dr. Cabot's "Better Doctoring for Less Money" appears. It almost makes our judgment final that acrid criticisms come from those whom the cap fits or from those inspired by false standards of ethics.

The assumption of knowledge in all branches of medicine is an admission of ignorance and to point out this fact should cause no great stir nor adverse criticism.

Let us get together in groups and clubs and put aside petty jealousies and work together for the common good. If we worked in harmony more and talked harmony less, advance in medical practice would be assured and unobstructed.

H. P. GREELEY, M.D.

### CHANGES IN THE MEDICAL CORPS, U. S. NAVY, FOR THE WEEK ENDING JUNE 24, 1916.

June 16: P. A. Surgeon J. A. Biello, detached from the *Kentucky* to home—wait orders.

P. A. Surgeon W. A. Bloedorn, detached from the Navy Yard, Washington, D. C., ordered to the *Kentucky*.

P. A. Surgeon P. T. Dessez, ordered to Navy Yard, Washington, D. C.

June 19: P. A. Surgeon F. G. Abeken, to Naval Hospital, Great Lakes, Ill.

Surgeon C. C. Grieve, detached from Naval Hospital, Great Lakes, Ill., and ordered to the *Utah*.

June 21: P. A. Surgeon G. C. Thomas, detached from Naval Station, Guam, and ordered to the *Fulton*.

P. A. Surgeon A. B. Hayward, ordered to the *New Orleans*.

P. A. Surgeon W. H. Connor, detached from the *Fulton*, and ordered to the *Kansas*.

### RECENT DEATHS.

DR. JETUS HAYDEN WOODWARD, who died in New York, N. Y., on July 2, was born in 1858 at Castleton, Vt. He graduated from Cornell University and the College of Physicians and Surgeons of Columbia University. He spent some time in studying abroad and at one time taught materia medica at the University of Vermont. As a specialist in disease of the eye, ear and throat he attained much prominence.

## Memorial Addresses.\*

DAVID WILLIAMS CHEEVER, A.M., M.D.,  
LL.D.

I.

By GEORGE W. GAY, M.D., BOSTON.

ANY eulogy of Dr. Cheever is to be limited only by good taste and discretion. It would be difficult to overestimate his sterling character, his high ideals, his pure motives, his strict integrity and his exceptional service to the profession. His life was replete with wise and efficient activities. For more than half a century he was held in the highest esteem by the leaders in the medical profession, the court of last resort in determining the character and ability of any physician. He has been so prominent in the medical world and for so long a period, that it is difficult for us to realize that we shall see him no more in his usual walks in life, the sick room, the hospital, the medical school and societies and in the community.

Born in Portsmouth, N. H., November 30, 1831, he died in Boston December 27, 1915, having just entered his eighty-fifth year. He was the son of Dr. Charles Augustus and Adeline (Haven) Cheever, and the grandson of Dr. Abijah Cheever of Revolutionary fame. He was prepared for college at home under private tutors and received a thorough drill in the classics, of which he was very fond, and which he continued to read in the original all his life.

\* Read at a meeting of the Boston Society for Medical Improvement, on April 3, 1916.

He entered Harvard College in 1848 and graduated four years later. Among his classmates was the Hon. Joseph H. Choate.

Descended from a long line of intellectual ancestors, born in a professional atmosphere, endowed with a well-balanced mind, a judicial temperament, a clear vision of duty and a devotion to ideals that nothing could discourage, he was peculiarly fitted for his future successful career. He was proud of his lineage and justly so. He came from good old English and Colonial stock, than which there is none better. He was seventh in descent from the Puritan, Ezekiel Cheever, who came from Canterbury in 1637, was the first master of the Boston Latin School, and for seventy years a noted teacher in this vicinity. Dr. Cheever's father and grandfather were accomplished physicians and surgeons for their time and had extensive and varied experiences. With such a lineage and surrounded by such favoring influences, it was but natural that he should follow in the footsteps of his ancestors and enter the medical profession.

Graduating from college in 1852, he spent a year and a half in Europe, then entered the Harvard Medical School, from which he graduated in 1858 in a class of twenty, one-half of whom saw service in the Civil War, among whom was Dr. Cheever. During his pupillage he attended a summer term at the Boylston Medical School, a short-lived but very good school. Some of the teachers later became professors in the Harvard Medical School, among whom were Drs. E. H. Clark, Charles E. Buckingham and H. W. Williams. Evidently the time was not

ripe for more than one medical school in this city.

The impression seemed to prevail in those days that the internes at the Massachusetts General Hospital, the principal one in this part of the country, received their appointments chiefly through social and family influences. While such may have been, and doubtless was, the fact in many instances, yet it was by no means universal, as is shown by the incumbents. Dr. Cheever very likely shared in the prevailing opinions, for instead of applying at that hospital for the position of house officer, he sought and obtained that of house pupil at the State Hospital at Rainsford Island, where he remained one year before taking his degree and received an excellent training under Dr. Lothrop in medical, surgical, contagious, venereal, children's, and all the diseases found in a large general hospital. There was a maternity department and also a smallpox pavilion. The house pupils prepared and dispensed medicines, made autopsies, dissected and prepared skeletons and had a varied and valuable experience which gave them an unusual preparation for entering general practice.

Dr. Cheever's professional growth was steady and continuous. Soon after his graduation he received the appointment of demonstrator in anatomy at the Harvard Medical School, a position that he held for eight years, thereby laying a firm foundation for his future brilliant career as a surgeon and a teacher. From the demonstratorship he became adjunct professor and then professor of clinical surgery. Later he was appointed professor of surgery, which position he held for ten years, to the great satisfaction of all concerned. He was made professor emeritus in 1893 and Dr. Warren succeeded to the chair in surgery.

In the early years Dr. Cheever did whatever came to hand, as most beginners in our profession are obliged to do. To eke out a small income, he wrote for some of the leading magazines, as the *Atlantic Monthly*, the *North American Review*, and he wrote the Boylston Prize Essay, all of which brought in much-needed money. He served at the Boston Dispensary as surgeon for five years, attended the patients in a smallpox hospital for a year and led a very busy life, if not a very lucrative one; that was to come later. He was a frequent contributor to the medical journals, published a volume of Surgical Lectures of lasting value and interest, and for twenty-five years was the principal editor and instigator of the medical and surgical reports of the Boston City Hospital, reports that he was instrumental in establishing. He served his alma mater for twelve years as overseer, and for an equal length of time was a trustee of the Mt. Auburn Cemetery. While occupying the latter position he became interested in cremation and exerted himself to establish a crematory there. This was accomplished, and he showed

his consistency by directing that his body should be disposed of in that way.

When the Boston City Hospital was opened in 1864, Dr. Cheever was appointed visiting surgeon, the youngest on the surgical staff. This position, in conjunction with that of prosector in the school, gave him an unlimited field for the development of his powers. How well he improved his opportunities is now a matter of history. For fifty-two years he was connected with the institution and was the last surviving member of the original surgical staff. During his active career he was a leader in the staff's activities. He inaugurated the surgical clinics; he established or encouraged the Sunday conferences of the visiting surgeons, a most interesting and useful function; he fostered public operating days; attended and took an active part in the clinical meetings of the staff and invited the outside physicians to visit the hospital freely and frequently for the purpose of familiarizing themselves with the work of the institution. In short, he was foremost in every effort to develop the hospital and place it in the front rank of municipal activities. Two novel features of this institution always excited his heartiest commendation; those were, first, the privilege granted by the trustees to the staff to nominate their own colleagues, and second, the competitive examinations of house officers. In his opinion these features conduced very materially to the harmony and efficiency of the staff and the welfare of the hospital.

He always considered that his hospital patients had prior claim upon his time and attention. He could turn his private patients over to an assistant, but, as they had no junior visiting surgeons in those days, he and he alone was responsible for the former class and must do the work. He was appointed for that purpose. The visiting surgeon had from sixty to one hundred patients under his care. He did all the operating and made many of the complicated dressings. Dr. Cheever was especially attentive in his after-care of serious operations, feeling that the results not infrequently depended thereon. Temperamentally he was a caretaker. He showed this trait not only towards his patients and friends, but also to the house officers and the nurses. He looked after their health and comfort, as well as their daily work. His thoughtful consideration won their respect and admiration. It was his invariable custom to treat his charity patients with the same care and consideration that he bestowed in his private practice. The quality of service was alike in both.

His career as a general practitioner was marked by the same broad grasp of the situation and the close attention to details that characterized his surgical work. He was, as before mentioned, a natural-born caretaker, and his interest was by no means limited to the sick. It extended to every one with whom he was

brought in close contact. He noticed everything and was ready with suggestions appropriate for the occasion. As might be expected, his patients had unbounded confidence in him, and many became his lifelong friends. He was, indeed, a tower of strength in times of trouble.

As a surgeon Dr. Cheever was safe, enterprising and dependable. Painstaking in arriving at a diagnosis, deliberate and careful in his operations, bold in emergencies, fruitful in resources, thorough in his work and most assiduous in the after-care of his operative cases, he long occupied a foremost rank in this branch of the profession. He did many bold, original or unusual operations that gave him an international reputation. He never forgot patients whom he had treated for a serious illness, or upon whom he had performed an important operation. He kept track of them as long as possible, thereby accumulating a mass of knowledge that was of great service in making him a broad-minded, efficient practitioner and consultant. He was a constant attendant at medical meetings, speaking and presenting papers frequently, a large number of which are to be found in the current medical literature of the time. He believed that papers worthy of presentation to a medical society should be published, and acted upon that principle, to the benefit of the profession and the public.

As a teacher in the medical school Dr. Cheever made a lasting impression upon the thirty-three classes of students that received his instruction. Plain, practical facts formed the basis of his teaching. In his opinion "pre-digestion, terseness and extemporaneous speaking" were the elements of his success in that work. Realizing the fact that most of his students were to earn their living by caring for the sick and injured, he endeavored to fit them for that task in the best possible manner. He had unbounded respect for facts; less for theories. Above all else, he was practical. Given such and such conditions, what are the proper measures to be taken to correct them, so far as may be? That is the sum and substance of practical instruction in our profession. He heartily approved of the suggestion that the Harvard Medical School should demand and provide a hospital service, as one of the requisites for graduation. It is to be hoped that some such scheme can be established in the near future.

Dr. Cheever was an active factor in the re-organization of the Harvard Medical School in 1871, when the present efficient graded course of instruction and examination was inaugurated. He supported President Eliot loyally in this struggle and lived to see the fruits of the wise movement. It was a great advance in medical education, and the promoters thereof may well be proud of their work.

The doctor was a public-spirited citizen, deeply interested in and thoroughly informed upon current events. Independent in politics,

but usually voting with the Republicans, except when he thought they strayed too far from the right course. He did his own thinking, formed his own opinions, had the courage of his convictions and acted in accordance therewith honestly and fearlessly.

Considering the fact that he was never rugged, physically, the amount of work that he was able to accomplish was marvelous. Five feet ten inches in height and weighing one hundred and thirty pounds, pale complexion, subject more or less to dyspepsia, which disappeared at sixty, on giving up meat, he lost little time by reason of ill health, until 1885 when he contracted septicaemia (blood poisoning) and was more or less incapacitated for a year. His capacity for work depended in no slight degree upon his serene temperament, his latent endurance, his complete self-control and the careful regulation of his daily life. He never made "coat-tail" visits, but, in accordance with a hint from his friend and teacher, Dr. James Jackson, one of America's wisest physicians, he always removed his overcoat and showed no haste until he was out of the house. No time was wasted, but his patients would not suspect that he had more work than he could easily attend to, or that he was in haste to get away.

Physicians should not have impulses, or, having them, they should not be acted on, until they have been subjected to the alembic of reason. Many a mistake is due to the neglect of this precaution. Dr. Cheever never acted upon impulse. He was a typical example of wise preparedness. It was one of his fundamental principles of life. It was his custom to review the steps of all important operations and to lay out the plan of his lectures the evening before. He never depended upon the inspiration of the occasion for what he should do, or say. So far as possible, he was thoroughly prepared for all emergencies. His foresight and forethought prevented mistakes, inspired confidence and insured favorable results. He was deliberate in forming his opinions, but once formed, they would stand rigid examination.

The doctor took a lively interest in the substitution of the present system of medical examiners for the old and oftentimes disgraceful coroner system, in which medical problems were left for decision to laymen who were paid by the job. Business, rather than justice, seemed the ruling motive in many instances. A flagrant case in which a young and innocent woman, a patient of the doctor's, was disgraced, another honorable physician insulted and humiliated and the family and friends distressed beyond measure was the final straw that roused public indignation and swept the system out of existence in this state.

Our friend was an effective speaker before legislative committees. Calm, deliberate, sensible, his remarks always carried conviction to reasonable persons. They could see at once that

he had no axe to grind, but was sincere, fair and unprejudiced. At one time he appeared, as an expert, in court frequently and, while he was an excellent witness for the truth, yet he considered it the most unsatisfactory of all his activities. To quote his own words, "I can almost say that I never left the court after testifying with a feeling of honorable satisfaction, or that I had been allowed to tell the exact truth after complicated questions and having my mouth shut by technicalities." He was an admirable witness for the right side, but he could not be swerved a hair from the truth, as he understood it. Upon the witness stand he was calm, collected, never lost his head nor his temper; simply answered questions in the shortest possible manner, volunteered no remarks or comments and left the impression of unbiased, disinterested evidence.

The doctor firmly believed that in important cases the court should be authorized to summon an expert, as now may be done in this state in criminal cases in which the sanity of the defendant is an issue. At present, medical expert testimony is bought and paid for irrespective of justice and regardless of the oath taken to "tell the truth, the whole truth and nothing but the truth," a resonant fiction sanctioned only by long usage. Cross-examination is supposed by the uninitiated to have for its object the elucidation of the truth, rather than the confusion of the witness and the jury. Dr. Cheever finally refused to accept this sort of service and appeared in court only when legally required to do so.

Dr. Cheever devoted no small portion of his active career to the service of medical charity in private as well as in his hospital practice. He fully appreciated the fact that medical charity is abused in our hospitals and dispensaries, and that thus far the efforts for its correction have been only partly successful. Paternal legislation takes no heed of the doctor who is required to care for the injured who are placed in our public hospitals by the insurance companies, and a movement is now on foot to include the sick in this class. The hospital is paid, the patient is paid, but the doctor gets nothing, although his services are the chief factor in the transaction. As Dr. Cheever has well said, "Hospitals impoverish the doctor and enrich the public. Hospitals benefit the professional knowledge and pick the professional pocket. . . Whom does the abuse of medical charity injure? It breeds pauperism and it robs the doctor." "To adjust the very delicate balance between our duty and our rights, between the abuse of our charity and our right to earn a living, is now a pressing and a daily problem."

Among his numerous charitable activities, Dr. Cheever established a scholarship in the Harvard Medical School for the benefit of deserving first year students, at that time the only one in

the institution for that class. He also gave a fund to the Boston City Hospital for the benefit of the graduates of the surgical department of that institution. For many years he was president of the Massachusetts Medical Benevolent Society which furnishes aid to needy physicians and their families. He was a liberal contributor to its funds and retained his interest in the society throughout his professional life. His charities were numerous, and few worthy applicants were refused aid of some sort.

Unlike too many in our profession, the subject of this sketch was an excellent business man, safe, sound and conservative. He realized the fact that the time may come in the life of any one when a dollar will be his best friend. His charges were moderate and in strict accordance with the fee-table in vogue in this vicinity, which he helped to establish. He was prompt in presenting and collecting his bills. His investments were safe and judicious and largely in live real estate in his home city, where it was under his personal observation. Speculation, promotions and "wild cats" had no temptation for him; safety and stability were his guiding principles.

His business operations were conducted upon the same high, ethical plane, as were his professional activities. In his opinion no transaction was really profitable unless it was profitable for both parties. For lasting results there must be reasonable satisfaction on both sides. He took much interest in the up-keep of his properties. For several years he had made it a practice to visit frequently every building that he owned, usually on Sunday, and took pride in calling attention to their excellent condition as regards repairs and hygiene. No liquor was allowed to be sold on his premises under any circumstances, a fact that diminished his income considerably. He was unalterably opposed to the traffic, as he, like every physician, was well aware of the evil results of the abuse of alcohol, and he would have no part in the business even as a landlord.

The professional and financial career of his many students always interested him deeply. He kept track of them so far as possible; his advice and encouragement were always at their service. As he has so truthfully said, "The welfare of my medical brethren has been in my thoughts prominently and permanently. I have tried to advance our profession." In the opinion of the writer, a physician beginning practice with nothing except a debt, who arrives at a stage in his career when he can live on his income without work, has achieved a financial success. Too few in our profession ever reach that situation. Dr. Cheever was fortunate in that respect, as in many others. Although he was eleven years in reaching his carriage, yet he was laying the while a foundation that brooked no reverses and his financial growth was as steady and complete as was his professional development.

Dr. Cheever's devotion to his profession was a precursor of his success. His whole time and strength were given to his work. His motto was, "Difficulty, Struggle, Progress." Beneath that calm, modest exterior was a will of iron and a determination that brooked no defeat. Nothing was permitted to interfere with his professional duties. He was always at the service of his patients and his fellow practitioners. As he has so tersely said: "Whatever success I have won as a doctor has been due to a peculiar quality of my mind, concentration; one thing; only one thing; always one thing. A doctor; only a doctor; always a doctor. One school; one hospital; one pursuit; one profession. That has been my rule and my course." Such was his life-work, as he summed it up, and its results are known of all men.

When Dr. Cheever had passed the zenith of his activities, the writer once asked him if he would choose the same profession again in the light of his experience. After a little hesitation, so characteristic of him, he replied, "I think I should, as I am better adapted for the medical profession than for any other calling." Happy indeed must any one be who can say at the close of a long career that he made no mistake in choosing his vocation.

Dr. Arthur B. Emmons, 2d, in his interesting paper on "The Profession of Medicine," has shown that the graduates of the Harvard Medical School are, as a rule, very well satisfied with their choice of an occupation. In reply to a similar question, 226 replied in the affirmative and only 16 in the negative. At the writer's last interview with the subject of this sketch he spoke of this paper with much interest. It had been read to him and had received his usual careful consideration. He thought that the prospects of the general practitioner were less promising than formerly by reason of the great increase in hospitals, dispensaries, specialists, and the paternal and socialistic trend of present-day legislation. He was not at all misanthropic in his views, and he believed that the situation would work out in the right way in time. It simply remained for us to accommodate ourselves to conditions as they came along. He had unbounded faith in the nobility of his profession.

Dr. Cheever was a forceful advocate of privileged communications between physician and patient and wrote and spoke thereon upon every appropriate occasion. Except in criminal cases, he claimed that the patient's record should be held sacred; that if justice demanded its revelation, it should be given privately before the judge rather than in open court. It may be needless to say that no inconsiderable proportion of the profession agrees with him in that opinion.

The medical defence act of the Massachusetts Medical Society, a species of mutual insurance against blackmail, met with Dr. Cheever's ap-

proval. By this act, counsel is furnished to the members, free of charge, in their defence in any fake suit that may be brought for alleged malpractice. In effect it discourages shysters in their efforts to secure hush money from physicians by threatening suits. The act costs less than twelve cents, annually, per capita, and has proven itself beneficial here, as it has done in twenty-four other state medical societies. It has evidently come to stay.

The recreations of our friend were walking, rowing, fishing, horseback-riding and the gymnasium. He was also fond of music and travel. He made several trips to Europe, taking much interest in art, and especially in sculpture. Rome was especially enticing on that account. Scenery upon a large scale had peculiar attractions for him. For twenty-one years his summers were spent in Cohasset upon a bluff overlooking the ocean, giving a view of which he never tired. In his fishing trips it was of little importance to him whether he caught anything or not; it was the open air, the vast expanse of water and sky with their endless changes that appealed to him. The loss of a daughter from drowning, the saddest bereavement of his life, sent the family to a farm in Dedham for the subsequent seasons. Here he took great interest in the various activities about him. His children and grandchildren were a source of never-failing delight to him. Dr. and Mrs. Whitesides' children from Portland, Oregon, spent their summers at Dedham and there was "something doing" all the time. The writer had the pleasure of giving Dr. Cheever his first ride in an automobile. The cold wind and his efforts to save his hat were far more in evidence, than was any enthusiasm over the trip!

While Dr. Cheever was not a religious man in the ordinary acceptance of the term, yet he was deeply reverent. His mind was essentially scientific, and that is usually reverent, less frequently religious. As he so well says, "Research widens the view and breeds reverence, not for myths and legends, but for infinite facts. Knowledge grows always. Medicine has a religion of its own, useful, immediate, daily. With reverence for what it cannot understand, it takes up and pursues its daily tasks with patience and in the love of man, with the hopes for more knowledge, more usefulness, and these are fulfilled in the succeeding generations."

Many years ago, while performing a critical operation upon a woman's neck, the patient suddenly collapsed from an air embolism (air in the veins), and for a few moments was apparently dead. Under appropriate measures she rallied, the operation was completed and the patient was sent to the ward. Turning to his house officers, Dr. Cheever said, "Where was that woman during those few moments, when, to all outward appearances she was dead?" The world has been asking that question ever since time began! Upon another occasion, while enjoying

a magnificent view in the Adirondacks, he called his daughter's attention to a beautiful flower growing at their feet, and said, "The Power that makes that flower grow upon this mountain can be trusted. Whatever the future holds is right." That he fully realized the comfort and support to be derived from religion under certain circumstances is shown by the following quotation from his writings: "No one can appreciate or bear warmer testimony to the good influence of the offices of the church on the poor sufferer's mind in preparing him for an operation, or some desperate struggle for life, than the hospital doctor. Calmness and fortitude displace fear; the mind is made up; confidence assured, and this is half the battle. The priest always sides with the doctor. His services are invaluable." A mind of the caliber of Dr. Cheever's could but meditate deeply upon these subjects. He was too wise, too logical and too reverential to doubt for one moment all the attributes of entire trust in a Supreme Being.

Even were this the time and place, the writer could hardly trust himself to trespass upon your time and patience by alluding to any extent to his personal relations with Dr. Cheever, which began in 1864, and terminated only with his life, a period of more than half a century. I saw him first in the front row of seats reserved for physicians in the old operating room in the cupola of the Massachusetts General Hospital. A slender, fair haired, neatly dressed young man with his hand done up in a black silk handkerchief, Dr. Cheever was recovering from a septic wound of the finger. Our acquaintance began in the old dissecting room in North Grove Street; then came a year as house pupil at Rainsford Island under his chum and classmate, Dr. George L. Underwood, next as his house surgeon at the City Hospital, then surgeon to outpatients, on his recommendation, and finally his colleague, as visiting surgeon, to the close of our active professional lives. As an example, an adviser and a friend, he was all that could be desired: faithful, loyal, reliable under all circumstances. Even at our last interview, a few days previous to the onset of his final illness, he gave me valuable advice relating to the curtailment of certain activities, with all the alertness and interest of half a century's duration. Truly, such friendships make life worth the having. One is tempted to linger over these pleasant reminiscences, but memory alone must suffice for the present.

Dr. Cheever was dignified, reserved, even austere in the opinion of those who had only a slight acquaintance, yet those having a closer relation found him most cordial, genial and sociable. He had a keen sense of humor and was quick to see the inconsistencies of people. He was kindly in his criticism, lenient in his judgment of human frailties, but not of crime or brutality. Justice was a cardinal principle with him, and he believed in human responsi-

bility. The writer has permission to quote the following tribute to Dr. Cheever's character from a personal letter from Dr. Henry P. Walcott: "Dr. Cheever has always represented to my mind the best example of a model for our profession; he appeared so to me when I first came in contact with him as prosector in the school, and when he rose to his high eminence, he lost none of his high leadership. We are too apt, I think, to complain of a degeneracy in our people, and whatever our failings may be, and I know that they are many, yet I think of no man who at any time better represents the strong characteristic of our race than did he. It adds to our confidence in the future that we have had such a man in our day."

While we may not intrude too much upon the home life of Dr. Cheever, yet we may be permitted to note the fact that it was all that could be desired. Unselfish, kindly, just, full of tender consideration for each and all, he was an ideal husband, father, companion. His married life of over fifty-five years is a blessed memory in the household. His chief pleasure was found in the family, and always to be shared with its members. He was essentially domestic. While he took keen enjoyment in the companionship of patients and friends, yet the home life was the principal refuge for rest and comfort.

Fortunate, indeed, was Dr. Cheever in having a son who, in every respect, is worthy of the name and who, as a member of the surgical staff of the Peter Bent Brigham Hospital, will sustain the enviable reputation of his ancestors. His three sons were a source of great satisfaction to the grandfather, not only for their personalities, but for the fact that they will carry the name on to future generations. While Dr. Cheever naturally regretted the absence of his son during his last illness, yet it was not unexpected, or unprovided for. He urged him to take the position as head of the Second Harvard Unit for service in the hospitals in France, realizing that he might never see him again. He regarded this action of his son as his final contribution to the great struggle for humanity now being waged in Europe. He often spoke of his gratification in the fact that a representative of his family was "doing his bit" in relieving the sufferings of the soldiers in France.

The increasing disability incident to his age was a sore trial to Dr. Cheever, who had been so active, but he bore it in silence and preserved his usual calm exterior to the last. For three or four years he had been unable to do much reading by reason of cataracts, and was, therefore, obliged to depend upon his secretary or some member of the family to supply the deficiency. He had also been warned by certain symptoms that his heart was not doing its work with its usual efficiency. He was advised to lay aside his favorite cornob pipe. Notwithstanding these infirmities, however, he was able to be out and about until near the end of his life. His last days were reasonably free from suffering.

About a week before his death he was attacked with the "old man's friend," pleuropneumonia, and went to bed for the last time. He received the most attentive and skilful care of Dr. Henry Jackson, the son of his old teacher and friend, Dr. J. B. S. Jackson, for whom he always entertained the highest esteem, not only for his mental acumen, but also for his kind heart and strict integrity; a fine type of the old school physician.

Dr. Cheever conferred freely with his physician from day to day as to his condition, fully realizing the situation and accepting it calmly and philosophically, as we should expect him to do. His habitual consideration for the welfare of others never failed him. A couple of hours before he passed away he said to his daughter, "How is your mother bearing up under this? I don't want you to leave her today." Although very weak, he then drew a check for prospective expenses and told his daughter to open the safe where she would find the pay envelopes for all the family employees properly sealed and labelled. "Pay those bills and come back and tell me when it is done." Soon after being told that his instructions had been carried out and realizing that he had attended to every possible detail, he closed his eyes in his last sleep, and all was over. In the language of his physician, "he died a king." He was Dr. Cheever to the last moment of his life; complete master of himself and of all his faculties. He died, as he had lived, quietly, bravely and thoughtful of others to the last. It was consistent with his life. It was ideal.

Few lives of eighty-four years are so sensible, so replete with good work, so completely under control, so well rounded out in all the essentials of true manhood, as was Dr. Cheever's. His sterling character, his high ideals, his strict integrity, his keen intellect, his sound judgment, his devotion to duty and his loyalty to his profession, all justify our highest appreciation. His career may well serve as an example, an inspiration to future generations of physicians.

Well done, good and faithful servant. You have fought the good fight; you have finished the course; you have solved the great mystery of the hereafter. We shall never see your like again, but your life's work will be admired and your memory will be revered by those who appreciate high character, noble service and all the sterling attributes that make for the development of the finest type of men, the upright citizen, the honorable, dependable physician.

## II.

By J. COLLINS WARREN, M.D., BOSTON.

My earliest recollections of Dr. Cheever date back to a period long before I had even thought of studying medicine. My father had gone to Portsmouth, N. H., to see a case in consultation

with the elder Cheever and had taken me with him. While the two surgeons were absent on their professional duties, I, a boy ten years of age, was entrusted to the care of the son, a young man who had just returned from Harvard where he had recently graduated. I can still recall distinctly the impression made upon me at that time. A tall and slender youth with quiet and sympathetic demeanor, he was conscientiously carrying out his father's orders to entertain the child in a suitable manner, in which effort he was eminently successful. Although no special exertions were manifest on his part to make himself agreeable, the time passed for me only too rapidly.

On the return of the doctors, the dutiful son was asked to array himself in a costume, in which he was to appear that evening at some social or public function. Young David disappeared and soon returned in the dress of a youthful Puritan. There still stands before me in my mind's eye the figure of a grave and dignified young graduate, fresh from four years of college life, the centre of an admiring circle amiably adapting himself once more to old family surroundings.

Since the curtain of memory first slowly fell on this little episode, the recollection of it has frequently come back to me in later years as a sort of prologue to the future relations—an entente cordiale—which were happily preserved in after life between teacher and pupil, and to the rôle which this representative of fine old New England stock was to play in the interesting medical drama, soon to be placed upon the stage.

Ten years and more had elapsed before I again came in contact with Dr. Cheever, now the full-fledged practitioner and teacher in the Medical School. As demonstrator of anatomy, he had charge of the personal instruction of the students under the supervision of Oliver Wendell Holmes. Having been given an opportunity to assist in the preparation of the dissection for the daily lecture, I enjoyed the privilege of coming into close contact both with the professor and his assistant. Of Holmes, Cheever says: "Wit, gentleness, keenness of intellect made Dr. Holmes a delightful master." Contrasted with the breezy ways of his senior were the quiet and business-like methods of the taciturn young man.

The holder of the office of demonstrator of anatomy had no sinecure in those days. The medical student was not of the type to which teachers of today are accustomed, but it proved an uphill job even for them to disturb the unruffled demeanor of their teacher.

I recall one occasion when the demonstrator's equanimity was put to a severe test. The dissecting room was in a semi-detached one-story structure, forming a low ell to the main building. It was lighted only from above. One quiet evening, while a section of the class was attending a demonstration by Dr. Cheever, a missile thrown by an unseen foe came crashing through

the brightly shining skylight. There was a moment's pause, no one daring to disturb the decorum of one of Cheever's exercises. I glanced with much interest at our instructor to see what effect this extra-mural demonstration would have upon him. After one look at the dilapidated ceiling he turned to the class, and in the words of his dual prototype calmly gave the order: "Up guards and at them!" Needless to add that the class promptly responded to the call, but not before a discreet enemy had been lost in the darkness of the night.

Dr. Cheever was a popular teacher, for though his manner often seemed cold and reserved, there lay beneath a saving sense of humor, so efficacious an antidote in time of tension. There was always a feeling of perfect confidence by the class in the justness of his decisions. (To the close of his career as a teacher, he retained a tender interest in the welfare of his pupils, as is shown in the foundation at the time of his retirement of the Cheever Scholarship,—the first of its kind—for young men entering the Medical School).

After serving eight years as demonstrator he was appointed adjunct Professor of Clinical Surgery in 1868, and this was followed by further promotion to a professorship of clinical surgery in 1875. It is difficult to appreciate at the present time the full meaning of this recognition of his ability as a surgeon and teacher, and of his standing in the profession.

The foundation of the City Hospital had been looked upon with suspicion by the powers that were of that time, and there was certainly no favoritism in the selection of Dr. Cheever to fill a prominent position in the surgical department of the Harvard Medical School. The teaching staff of surgery would not have been complete without him, and so, with no fear or favor, he rose steadily from one position to another, being made Professor of Clinical Surgery in 1875, and finally, upon the retirement of Dr. Bigelow, the head of the department as Professor of Surgery in 1882.

It is interesting in this connection to glance at a list of the subjects which constituted the course of lectures given by the Professor of Surgery in 1888, as shown in a printed list of the winter's course which lies before me. It covers the same ground as that of his predecessor, and is practically a surgery of the systems. Surgery was only just beginning to claim its share of internal medicine, and as new regions were invaded by pioneers from time to time, the teaching of these new chapters of surgery was relegated to the younger members of the department.

There was no one of the surgical staff at the School who could, however, compare with him as a teacher. Dr. Bigelow's personality had always contributed largely to the prestige of the surgical department in the School, and his course of lectures was always characteristically punctuated by one or two of the interesting or

brilliant episodes, with which that distinguished teacher knew only too well how to garnish them. But Cheever's lectures were marked by a clock-work-like precision, by which the ground laid out beforehand was covered systematically from beginning to end. A cool and clear head, a reposeful manner showing the speaker to be perfectly at his ease, a well modulated voice and simplicity of diction (qualities alas, but too rare in lecturers of our profession) combined to enable Dr. Cheever to hold the attention of his class from start to finish.

Lasting proof in the accuracy of this statement is given in that admirable book containing his published course of lectures, which were taken down verbatim by the stenographer and printed subsequently almost as a phonographic record.

Needless to say that the attendance at Dr. Cheever's lectures was always a large one, and that great regret was manifested by the students at his retirement, which occurred in 1893. For many years after this, as emeritus professor, he was invited to give a few lectures on subjects of his own choosing to gratify succeeding classes, who had been disappointed in not being able to count themselves his pupils.

This quality as a teacher enabled him to shine conspicuously at the bedside in clinical instruction. I well recall certain Sunday morning visits at the City Hospital, which I had the privilege of attending after entering upon the practice of my profession. These were models of what such visits should be. No extraneous matter was injected into these talks. There was no wandering from the point which each particular case illustrated, and the story and its moral were told in the fewest possible words, the patient and not the doctor being always kept in evidence.

As I have already intimated, our relation—first that of pupil and teacher, and later of assistant on the teaching staff—were always regarded by me as leaving nothing to be desired. The elder man always took a sympathetic interest in his junior's welfare. No occasion calling for a word of encouragement or congratulation was ever passed unnoticed; and if criticism was necessary, it was always skilfully concealed under the guise of a fatherly suggestion.

I have often wondered whether the current of academic waters flowed as smoothly in other departments of the University as they did in ours while he was chief. Perhaps it was because his depth of character brought a serenity with it which permeated the whole staff, one and all of whom were glad to acknowledge him as their leader.

Through all the period which I have attempted to cover in the course of this personal sketch, the estimate of the man which had impressed itself so forcibly on the child, still seemed to hold true. In whatever rôle he might appear in after life, either as the bold surgeon, or the unflinching leader in a good cause, or the quiet

gentleman in somber clothing on his daily rounds, I seemed still to see the garb which was so typical of his ancestry and his character. And when, at the recent Convocation of the American College of Surgeons, the honorary degree of the college was conferred upon him, I saw him for the last time in the robe of the order, he seemed to me to have come into his own again. The somber folds of the academic gown seemed to serve as a fitting setting to the grave and intellectual features of the man and while, during a pause in the proceedings arranged to allow him to retire, he passed slowly down the aisle, leaning upon a proffered arm, his assembled colleagues rose as one man to do him honor as a recognized leader in their chosen profession.

### JAMES CLARKE WHITE, M.D.

#### I.

By ABNER POST, M.D., BOSTON.

DR. WHITE was so well known as a dermatologist, that comparatively few know the varied activities of his earlier life. He, somewhat unconsciously, fitted himself for the study of medicine during his boyhood and college years. It is very striking that he devoted himself of his own volition, before he even knew what his future life would be, to those preparatory studies which are now required of students entering upon the study of medicine. In his undergraduate diary, he wrote, at the end of his junior year: "I have done much work outside the curriculum in natural history—in botany and ornithology especially—fascinating studies under such teachers as Gray and Wyman." During vacations, he shot and stuffed birds for the college Natural History Society. He refers in his diary to Webster's post-mortem and to walks of his class with Agassiz; of being excused from recitation at the advice of the president to attend an auction of stuffed birds. On May 15, 1853, the latter half of his senior year, he wrote in his diary: "There came to me this afternoon in church the sudden conviction that I would choose medicine as my life work."

In the first two years of his medical course, he spent much time in the study of chemistry. Professor Cooke fitted up a small laboratory for students and in this laboratory, Dr. White gained "a considerable knowledge," as he said, "in analytical and physiological chemistry." He analyzed the Warren collection of urinary calculi and wrote an essay based on that work which received the Boylston Society's prize.

In 1855, he was appointed house pupil at the Massachusetts General Hospital, on the medical side, with Drs. J. B. S. Jackson, D. Humphrey Storer and Henry I. Bowditch as his visiting

physicians. George S. Hyde was the other medical, and Lucius Manlius Sargent, Jr., and Alfred Hosmer, the two surgical house pupils.

At the end of this year's hospital service, he returned to the chemical laboratory for two months and in August sailed for study in Europe, going to Vienna instead of Paris, on the advice of Professor Calvin Ellis. In Vienna, he devoted himself to general medicine, but especially to the study of skin diseases, as he says, "perhaps because I felt that I had more to learn in this than in other branches of medicine and that facilities for their study were so extraordinary, rather than with any intention of making it an exclusive field of practice."

A description of Hebra, which he made some years later, shows the impression that great teacher made upon him: "There (in Vienna) they found a man teaching skin diseases as they had never been taught before, with unlimited means of clinical illustration, with the keenest eyes for observation, with an unbounded amount of information drawn from many years of experience, with a self-restraint which no desire for premature fame could tempt into hasty publication, and with a sound and logical mind, the chief of the German school of dermatology—Professor Hebra. Under his personal tuition, they were taught to study diseases of the skin by the simple methods of observation which the naturalist employs upon objects of nature."

The memory of those Vienna days was kept alive by a club of six men who had studied there together.—Drs. Hay, H. K. Oliver, B. J. Jeffries, Hasket Derby, F. B. Sprague and J. C. White. They dined together regularly and a photograph of the group occupied a prominent place on Dr. White's office wall.

On his return to Boston, he entered upon general practice with an office in Hotel Pelham, very recently demolished, and a little later after his marriage, in Park Square.

In 1858, he was appointed Instructor in Chemistry, and in 1866 Adjunct Professor, and while holding that office he made examinations for the Government in all capital cases, and gave his testimony with such impartiality that he was seldom cross-examined.

In 1871, on the resignation of Professor Bacon from the Chair of Chemistry, Dr. White declined further advancement as a teacher in that branch. He had already been appointed visiting physician at the Massachusetts General Hospital and his growing practice, especially in skin diseases, demanded the greater part of his time. That same year, a dermatological department was established at the hospital under his charge and he was appointed Professor of Dermatology in the Harvard School—a chair especially established for him and which he held until 1902.

To his value as a teacher, most of us here can bear witness; of the regard in which he was held by his dermatological associates, one cannot do better than quote a few paragraphs from

an obituary notice in the *Journal of Dermatology*:

"The influence of the pioneers in dermatology must not be underestimated, and foremost among them stands the figure of James Clarke White. Beginning at a time when specialties were unrecognized and repudiated, or at most, grudgingly acknowledged, he devoted himself to the task of showing that progress and the best results are to be obtained by concentration of energy and purpose along well-defined lines. This course required courage and pertinacity, with both of which qualities he was highly endowed. If the path of the specialist seems easy and natural nowadays, it must be remembered that those who mapped it out lived under far different conditions. The prejudices that had to be encountered are more than once touched upon by Dr. White in his reminiscences. But he was by nature truthful, fearless, and, like all strong characters, confident of himself and of his cause, and ready to defend it before any tribunal. These very qualities, which exposed him, perhaps, to the occasional criticism of being dogmatic or controversial, were of inestimable value to the causes for which he labored. His influence at the meetings of the American Dermatological Association was always exerted in the direction of high progress, and his dignified example will be remembered with approbation by all his colleagues, even by those who were sometimes inclined to resent his uncompromising adherence to his principles."

Dr. White took his duties as Professor in the Medical School very seriously. The world owes him a debt of gratitude for his part in the reform, or better, the improvement of medical education. When he first became a teacher, the requirements for a degree were three years of nominal study with two courses of lectures, and medical schools were dependent upon the fees from these lecture courses for their existence. A small proportion of students supplemented these requirements by summer courses, but the actual requirements for a degree were very low, and there was a very genuine, though by no means universal, desire, in medical circles for a higher standard. Fruitless attempts had been made to unite the medical schools of the country in a combined effort to this effect, but in the absence of a central authority, they were unable to reconcile their varied ideas—and schools were obliged to act individually. If not the first, Harvard was among the first absolutely to reorganize its curriculum, but not without dissension among its faculty. It required faith in the future to believe that it was possible for an unendowed school so to raise its standards as to drive away more than half its scholars and still live. Into that reform, Dr. White threw his whole soul.

He was at that time editor of THE BOSTON MEDICAL AND SURGICAL JOURNAL and used the editorial pages to favor the reforms he so ardently wished.

It was the custom to open the winter's lecture course by an address from some one of the Faculty. This duty having fallen to Dr. White, he utilized the opportunity to make another plea for better instruction for students, and again, as anniversary orator of the Massachusetts Medical Society, he made to the general profession a similar plea. It is impossible to distribute properly the credit of this movement, but no one was more persistent in its advocacy than Dr. White. Neither is it easy, at this late day, to understand that it required courage. The improvement appears to us so logical and so necessary that it seems unbelievable that any opposition should have existed. The great hold which it took upon his life is shown by the great space devoted to it in his "Sketches of My Life."

It was a very natural sequence of Dr. White's interest in natural history that he should become a member of the Boston Society of Natural History. He served as its curator of comparative anatomy for ten years, from 1858 to 1868, and was a very active and efficient one. He secured the bodies and mounted the skeletons of the animals from an extensive menagerie, which had perished in a conflagration. There is a tradition at the Museum that Professor Agassiz appeared at the menagerie very soon after Dr. White had completed his bargain, and was very much disappointed at his failure to obtain the skeletons for the Museum at Cambridge. At the present time the Boston Museum is planning to limit its activities to the fauna of New England and the skeletons in question are being transferred to the Cambridge Museum, where Agassiz wished to see them. He also arranged a large collection of birds. He was interested in the construction of the present building at the corner of Berkeley and Boylston Streets.

Fifty years ago, the study of natural history was largely confined to physicians. They were the principal founders of the Boston Society of Natural History. Of its seven officers, chosen at its first meeting, six were physicians. Dr. White was also a member of the American Academy of Arts and Sciences when the same men who were prominent in the Natural History Society, discussed Darwin's doctrine of natural selection.

Dr. White had always the good of the profession as a whole at heart. He did much to bring about mutual acquaintance and confidence between its members. In his address as first president of the American Dermatological Association, he said:

"The little differences of opinion, personal jealousies, and even malicious criticisms, which are so apt to occur among physicians, to the

detriment of science, arise largely from mutual misunderstanding and would be far less prevalent if the parties knew each other better." And, twenty years later, in another address, he said: "In that first address I expressed the hope that the dermatologists of this country, who lived widely apart and had been working without meeting each other, some of them for twenty years, would find great advantage in forming a mutual acquaintanceship and comparing and reconciling their individual opinions, often, previously, at unfortunate variance. Certainly we may congratulate ourselves that this most desirable aim has been completely fulfilled; that it is a sincere delight to meet one another at these yearly gatherings; that our respect and esteem for each other has been constantly strengthening during all these years and that we express and criticize our individual observations and beliefs with the utmost frankness without jarring in any measure our bonds of good fellowship."

The same desire to see us a brotherhood of scientific physicians rather than an aggregation of rival practitioners, was manifested among us here in his home. In his "Sketches" he speaks of the many pleasant acquaintances with physicians in all parts of the state, formed during his visits as President of the State Society to the district societies.

In the Massachusetts Medical Society, Dr. White was anniversary chairman, orator and president. He was the first president of the American Dermatological Association and held the same office at its twenty-first annual meeting, but the honor which must have given him the greatest satisfaction was the presidency of the International Dermatological Congress held in New York in 1907.

He was a polished and forceful writer, but many of his writings were on subjects of immediate interest,—addresses and editorials, which played an important part in the questions of the day. They all show evidence of a well-cultivated mind and of high and earnest purpose.

His contributions to dermatological literature were numerous, original and valuable. It is doubtful if he ever failed to contribute something of worth to every meeting of the Dermatological Association.

His book on "Dermatitis Venenata" filled a gap in medical literature. His knowledge of botany and chemistry contributed largely to its value. It illustrates the usefulness to the profession of men with special knowledge in different scientific branches.

In 1914, he published privately and circulated among his friends an autobiography which he entitled "Sketches from My Life," of which mention has already been made. One sees in it the love of natural history and natural science as a guiding force from childhood to old age. It contains his diaries at Cambridge and in the

Medical School. In it he lives over the interesting activities in which his life had been passed and closes with an expression of contentment which must come to few.

No notice of Dr. White could be complete without reference to his personal appearance. He carried himself very erect, his dress was always immaculate, and he gave the impression of absolute cleanliness of body and soul. One could not associate anything common or unclean with his personality. This view of the man adds peculiar interest to a description of his first impression of one of the older of the Viennese professors: "He looked as though he had made a very hasty toilette, had forgotten his collar, and had not made the same use of the Danube as we do of the Cochituate," and it also shows that he was able to appreciate the man in spite of this first impression. His description continues: "The man himself has small, beady eyes beaming with fire and *bonhomie*. A great well of cunning and knowledge of the world lies hid therein. His hands, with which he reads such curious riddles of disease, any lady might envy for their shape."

I cannot close this tribute to Dr. White without an expression of my own affection, and with some hesitation I am going to relate an incident, trifling in itself, but revealing a side of his character unsuspected by those who met him only casually. It was my good fortune to cross the water with him in 1896 and to occupy the same state room—and the courtesy which he displayed can never be forgotten. Never for a moment did he forget my comfort. In particular, I recall one afternoon when I felt obliged to lie still upon the lounge—not quite sick but with a strong preference for a horizontal position and quiet. Three or four times Dr. White came to the room, softly opened his trunk, took up and replaced an article or two, asked if I wanted anything and retired. I could not see that he put anything into the trunk or took anything out. The sole object of his visit was his wish to do anything possible for my comfort and to conceal from me the real reason of his visit.

Dr. White died on January 5, 1916, at the age of 83. He had lived to see the reforms in teaching which he had urged so enthusiastically established, and the school which he loved take the high rank to which he aspired for it. He had seen his chosen specialty given its proper place in the medical curriculum everywhere. He had held all the honors his profession could bestow upon him. He left this world followed by the respect of all and the love of those who had known him.

## II.

By FREDERICK C. SHATTUCK, M.D., BOSTON.

FULL of years, full of honors, highly respected by profession and public alike, after an un-

usually rounded and successful life, James Clarke White has gone to his rest, leaving behind him an example which we very properly, and I trust fitly, emphasize this evening.

He was of Scotch-Irish stock, founders of Londonderry, New Hampshire, some of whom, moving to the Maine coast and mindful of their origin, called their place of settlement Belfast, another important Ulster town. Here, in 1833, our friend was born. One would not suspect that one of his great grandmothers was a Viennese, so characteristically Scotch-Irish were his qualities. It is perhaps well that he was one of a family of seven children, an education in itself. His father was shipbuilder, ship owner, manufacturer, bank president, a leader in all the activities of the town and the country round about. James, fifth child and eldest son, took his A.B. at Harvard in 1853, member of a class prolific in professors, his M.D. in '55, after service as house pupil in the Massachusetts General Hospital. Up to this time Paris had been the Mecca of the aspiring young American man of medicine. White was among the first Americans who broke away from this tradition, encouraged to do so by the suggestion of Calvin Ellis, who had lately visited Vienna, and recognized the advantages offered by that group of remarkable men,—Oppolzer, Skoda, Rokitsansky and Hebra. In this step he showed a characteristic trait, that of doing his own thinking. After a year in Europe, a year which all who knew him are sure was filled with diligent purpose alike in purely professional and in general improvement, he settled in general practice in Boston. In dermatology and medical chemistry he had qualified himself especially. His character, his knowledge, and his readiness to use them fully wherever service could be rendered, met with prompt recognition.

My earliest personal recollections of him go back to the middle '60s, when he was Adjunct Professor of Chemistry. My father was then Dean of the Medical School, and the Faculty meetings were held at his house. After due attention to affairs of state, the physical ravages caused thereby were made good by a simple, stand-up supper of oysters, ice cream and wine. To these I was sometimes admitted, and did my best to save waste of food. My most vivid recollection of these meetings is Dr. White, who was always very kind to and considerate of the boy of the house. His manly, clear-complexioned face, his erect form, the conspicuous neatness of his well-cut clothes are all stamped in memory.

After I began to study medicine in '68 his teaching in chemistry and dermatology, and ward visits with him in the Massachusetts General Hospital, to which he was appointed Visiting Physician in 1871, occupy cells in my cerebral cortex which are still in commission. Soon after this came the parting of the ways.

As thorough a man as he could not slur work, and he had to reconcile or decide between the rival claims of general practice, medical chem-

istry, and dermatology. As a medico-legal expert he made it a rule to appear only for the Government, a practice which enhanced respect for the impartiality of his evidence. To all, no one man, even fifty years ago, could do justice. He chose dermatology, of which he was appointed Professor in 1871, and cut himself off from all other practice. It required great courage in those days to specialize in dermatology; indeed, in anything except ophthalmology. But courage is a quality of which Dr. White had, at least, his share, and his integrity of character was so well known that all understood there was no sham in his adoption of a specialty. It seems a pity that so many present day specialists start as such, instead of growing into specialism, as did White. Perhaps it is unavoidable, so intensively and extensively has knowledge opened up, above all in the last quarter of a century. The body is one, although its parts are many. General practice may be compared with the low power of the microscope. Dr. Owen Wister, of Philadelphia, remarked to me many years ago that "it takes a mighty big man to be a specialist." Dr. White was not what his great teacher, Hebra, used to call "a specialist by the grace of God." His specialism was based on a wide, general experience. On his work and eminence as a specialist I shall not dwell, nor on the very active part he played in medical education and its reform.

Behind the specialist is the physician, behind the physician the man. Dr. White was a virile, a very real man, and it is of him as such that I shall mainly speak. He knew how to play, as well as how to work. At one time he was a diligent frequenter of baseball matches. Always a lover of nature, he delighted in the mountains, the sea, the clouds. At one time no member of the Boston Society of Natural History was more active than he. Since my intimacy with him began, now some thirty years ago, it seems to me that birds and plants especially appealed to him. Every summer he kept a list of birds seen. During a visit to me in the Adirondaeks, he sought for and listed all plants bearing berries. He cared more for the beauty of the plant, its flower and fruit, than for intimate structure. I cannot remember ever seeing him use a pocket lens in the woods or fields. Of china he was fond and knew much. Here again his nature asserted itself, his hatred of sloppiness. His interest ran mainly to European and American china, recognizing that the whole field cannot be ploughed by a busy professional man.

He well knew what good food is, how to select and how to prepare it. I should say he was a bit of a gourmet, were I sure that I should be fully understood. His gastronomic tastes were catholic, but there were four things he couldn't, or wouldn't eat. Clams, melons, and pineapples, he eschewed because they disagreed with him. The pig to him was an unclean beast, and he would have none of him in any form. His baked beans, to which he was loyal, were married to

fat beef. Only a few years ago he was to dine with other friends at my house. Luckily I found out in time that all four of his taboos were on the proposed menu. He was a judge of wine, of which he had a careful and wisely selected cellar, much enjoying a good glass with friends. Cocktails and tobacco had no charms for him. When he took alcohol, he took it like a gentleman, in the form of wine, and with his dinner. He was a wide reader, with system in that, as in other things. He rarely slept after six, and got in an hour's reading before rising. Of the First Church he was an active member, serving on the Standing Committee for some time as Chairman, and on various other committees.

The society of his friends was a delight to him. He was always courteous and considerate of others, perhaps not quick to give his friendship, but once given it was firm as a rock. His social talents had wider scope as his time was freed from the Medical School, and the Hospital, and, finally, from private practice. Some of the leisure thus won resulted in his interesting "Sketches of My Life," and in his sketch of the Clarke-White family.

The last years of his life he passed the months of June to October at Islesboro in Penobscot Bay. His white house was on the crest of a ridge one hundred feet above the water, and contained collections of books, china, furniture, and pictures, which gave him great enjoyment, alike in collecting and in owning. The eupolia, to which he liked to lead the way, commanded both east and west bays, and more than twenty towns, among them Belfast, his birthplace, some ten miles away. On his west porch he passed much time, delighting in the ever-changing views of the Camden Hills, and the activities of Gilkey Harbor. No yacht entered or left unnoted by him. Many friends will cherish many memories of this porch, and regret that memories alone remain for them.

Of sentiment he rarely talked, but he had it abundantly.

Some we call good are so negatively, rather than positively. Not so Dr. White. Virile, fearless, aggressive, he was a good fighting man, good man of medicine, good citizen, good friend. An unusual degree of these by no means synonymous forms of goodness was happily and rarely blended in him.

He was a knight, *sans peur et sans reproche*. In life he stood for all that was best. Is there any better preparation for death, anything which one of us could more wish said of him? Let us honor him by striving to follow his example.

#### REMARKS.

DR. SPRAGUE: I wish to add a few words of a personal nature to the tribute to Dr. White, as coming from an old friend and contemporary. Dr. White and I were fellow students

in the Medical School, where we had a pleasant acquaintance, and afterwards met in Vienna, in 1856, where we roomed together for the greater part of a year. At that time Europe was not the familiar ground which it has since become to the American traveler and student, and Vienna seemed especially remote and strange, in truth a far country. This tended to increase our intimacy, an intimacy that has existed and thrived through all these succeeding years, although our paths have, in many respects, been in different directions. Dr. White at that time showed the qualities that in later life carried him so far. He had untiring energy, great industry, was a keen observer, and possessed of excellent judgment. He was always self-reliant, and had a strong personality that was evident to everyone who came in contact with him. He had a most retentive and accurate memory, and was often called upon by his intimates to refresh their recollections. He thought clearly and wrote exceedingly well, with a clearness and conciseness difficult to surpass. He was a keen critic, but never indulged in a carping spirit. He was always fair and above-board, and he had a generous admiration for talent shown by others or good work done by them in any direction. He had an independence that made him more willing to confer a benefit than to receive one. He had high standards and lived up to them. In his death his associates have lost a true friend, a genial companion, and a sterling gentleman.

#### EPIDEMIC POLIOMYELITIS. THE SYMPTOMATOLOGY AND DIAGNOSIS IN THE ACUTE STAGES.\*

BY FRANCIS R. FRASER, M.D., NEW YORK.

[From the Medical Clinic, Presbyterian Hospital, Columbia University, New York.]

THE evidence at present available on the manner of conveyance of the virus of acute poliomyelitis points to the importance of personal communication of the infection.<sup>1</sup>

Acute cases, recovered cases, mild cases, abortive cases and human contacts are all capable of conveying the infection. Any methods of isolation and quarantine that may be deemed necessary as preventative measures require for their efficient administration that all cases, including the abortive forms, should be recognized early.

The diagnosis of acute poliomyelitis is not of great difficulty after paralysis sets in, but is of

\* An abstract from lectures delivered to the medical profession in the State of Vermont during the summer of 1915, at the request of the State Board of Health.

extreme difficulty in the preparalytic period and in mild and abortive cases. The acute stages may be divided into four periods. There is first a period of incubation, when no symptoms are present and when the patient is apparently perfectly well. The length of the incubation period is difficult to ascertain, largely because of the difficulty of determining the source and time of infection, but has been variously computed to be from two to ten days, and may be as long as three weeks. A study of the experimental disease in monkeys, which simulates the disease in human beings very closely, shows that in monkeys there is an incubation period varying from three to forty-six days or longer. The second or preparalytic stage is marked by a sudden onset. From the statistics of the Vermont epidemic of 1914, it is found that of two hundred and eighty-four cases, one hundred and seventy gave a history of excellent health before this onset; in ninety-seven the health is recorded as good, and in eighteen as poor. The preparalytic period may be entirely absent, and this is commonly seen in the sporadic cases, but in epidemics it is almost always present. In one hundred and twelve cases admitted to the Hospital of the Rockefeller Institute during the years 1911-1913, in whom the time of onset of the preparalytic period could be definitely ascertained, the average duration of this period was over two days. The longest period in this series was fifteen days, although in a few cases the preparalytic and general symptoms have disappeared entirely for a few days, only to return with paralysis. The third period follows the second immediately, and is characterized by paralysis or weakness of muscles, in addition to the symptoms that characterize the earlier period. The paralysis may be developed suddenly without further spread, or the further involvement of muscles may continue for an indefinite period, usually for a few days only, and seldom for more than ten days. In the fourth period no further spread takes place; the patient's general symptoms are still present but are subsiding. This period occasionally ends sharply, as if by crisis, but is more often prolonged, the symptoms disappearing gradually. It may be many weeks before the pain and tenderness and other acute symptoms disappear. With this period the acute stages may be considered to end, and it is then the results of the disease that have to be dealt with.

The lack of definition of these periods is to be expected since they are defined by symptoms which are only the outward evidence of the disease process that is taking place in the body generally, and in the central nervous system in particular.

**Incidence.**—All classes of the community appear to be equally affected, and although the disease is commonest under the age of twenty, there does not seem to be any limit to the age

of the persons attacked. Two hundred and ninety cases in Vermont in 1914, grouped in age periods, show:

Under 1 year.....	0 cases
Between 1 and 2 years.....	37 "
Between 2 and 5 years.....	88 "
Between 5 and 10 years.....	75 "
Between 10 and 20 years.....	63 "
Over 20 years.....	27 "

That a history of excellent health immediately previous to the attack is the rule, has already been pointed out. Seasonal incidence has been the subject of much statistical study and, as in most epidemics in this country, so in the Vermont epidemic of 1914, the incidence was greatest during August.

**Symptomatology.**—1. Preparalytic and General. When the case is first seen by a physician the parents, as a rule, state that there was a sudden onset of feverishness, with drowsiness, general weakness, loss of appetite or vomiting, and perhaps irritability and restlessness. Frequently such a condition persists for two or three days before the attendants realize that something more than a mild disturbance of the digestion is present.

(a) Fever is always present at the onset in the epidemic cases. Temperatures as high as 104 and 105 are noted at the onset and in a few cases before death, but it is more usual to find temperatures of 101 to 103 swinging slightly, and gradually subsiding in the course of a few days. It is not unusual to find readings of 100° for many weeks after the acute attack is over and when recovery is well advanced. In a few cases, generally those in which the symptoms are indicative of lesions in the upper part of the central nervous system, a continuous fever of 103 or 104 is seen for three or four days, ending sharply in a crisis.

(b) The pulse rate follows the temperature, and any pronounced departure from this rule should lead to a search for some cause other than poliomyelitis.

(c) Gastro-intestinal disturbances are usually present and may predominate in the first few days. Loss of appetite is always present in the febrile stages, and the illness may be ushered in by vomiting. Profuse diarrhea is rare, and constipation is more often present and may be marked. The vomiting rarely persists after the first two or three days. Abdominal tenderness is often seen and is part of a generalized tenderness of muscles. This is especially the case where the abdominal muscles are paralyzed and, as with the paralysis, the tenderness may be localized to a part of the abdominal wall only.

(d) Preparalytic symptoms referable to the respiratory tract have been prevalent in a few epidemics, but this is unusual. It is not uncommon to find slight catarrh of the upper passages, and frequently the tonsils and pharynx have a slightly reddened and congested ap-

pearance. An acute tonsillitis and the formation of a membrane are so seldom seen that their presence would suggest another diagnosis. In cases where the pharyngeal muscles are paralyzed mucus and food collect in the pharynx, and by causing great distress may distract attention from the real cause of the condition. When paralysis appears, the respiratory system acquires a peculiar importance that will be discussed later.

(c) Frequently the first symptom to attract attention is a heaviness and drowsiness. In cases severely infected the patient appears to be in coma, but more frequently there is simply a desire to be left alone and a disinclination to play or to take part in activities of any nature. There is, however, no mental dulness, for when spoken to or aroused there is brightness and mental activity that is surprising. In fatal cases this mental alertness to the very end is a picture that is not readily forgotten when once seen.

(f) Accompanying this drowsiness there is an irritability, when roused, that is in striking contrast to the heaviness seen when the patient is left undisturbed. The child objects to any examination or handling, and the doctor is in more disfavor with his patient when dealing with acute poliomyelitis than with almost any other condition. This child may be ever so good-tempered and tolerant with strangers as a rule, but when suffering from acute poliomyelitis, the disposition is very constantly described by the parents as "cranky." With this mental irritability there is a physical restlessness. Sleep is broken and there is a constant tossing and moving from side to side. Delirium and convulsions are rare.

(g) Frequently the whole body jerks from time to time, but there are also seen sharp single jerking movements of a part of the body—of one limb or of one side of the face—or of several parts. It is noticed that the parts that show such jerking movements are frequently the parts that later become paralyzed. Such jerking movements may be due to irritation of the anterior horn cells before the cells are so damaged as to cause paralysis of the part.

(h) A diffuse generalized sweating is commonly seen in the very severe cases, and may continue both day and night for many weeks after convalescence is established. It is more profuse at night in such cases. As a rule, when present it is only during the febrile period. Less common is a localized sweating seen in a part that later becomes paralyzed. This phenomenon may be related to the jerking movements described above and to the association in the anterior horns of the gray matter of the cord of the motor cells and the cells governing the sweat functions.<sup>2</sup>

(i) In the early period before definite paralyzes are seen, there is apparently a general weakness of the musculature of the whole

body. When a patient recovers from the acute stage in a few days with little paralysis, the strength of the unaffected muscles is in marked contrast to the apparent weakness of the same muscle in the febrile period. It is difficult to estimate how much of this is due to lack of effort on the part of the patient, but this weakness is more marked than in other conditions with a similar degree of fever.

(j) Unlike other infectious diseases of childhood, acute poliomyelitis is accompanied by diffuse pain and tenderness. The child objects to being handled largely because of pain. There may be hyperesthesia of the skin, so that the lightest touch causes pain. In other cases, tenderness is not elicited until pressure is exerted on the deeper structures, especially the muscle masses. There is still a third degree of tenderness, when no pain is elicited until the part is moved, when stretching of the muscles, tendons and articular structures causes pain. The pain may be generalized throughout the body, or, as is usually the case, where passive movement is required to elicit it, it is present only in a part that is paralyzed or about to be paralyzed. Since the pressure of the bed or the attitude of the patient causes pressure on deep structures or stretches tendons and ligaments, it is difficult to ascertain that true spontaneous pain is present. Sometimes the most careful adjustment of a part to avoid pressure or tension fails to relieve the pain, even in older patients, who can cooperate so that the presence of spontaneous pain, as distinct from tenderness, appears to be demonstrated. Older patients who are able to analyze their symptoms, commonly complain of severe headache, and this may be the earliest symptom. The pain in such a case is usually not localized to any particular portion of the head.

(k) Pain in the back of the neck and in the back is an important symptom. This may be spontaneous, but is more often seen only on attempting antero-flexion of the neck and back. To prevent such flexion the muscles of the neck and back are held contracted and give the stiffness that is so characteristic and that early in the disease is suggestive of some lesion of the meninges or central nervous system. Opisthotonos may be present, but this degree of retraction is rare. The patient prefers to lie on one side so that the head may be held tilted slightly backwards, or on his back with a pillow beneath the shoulders so that the head falls back. The stiffness may not be noticeable until antero-flexion is attempted, when pain is complained of and the protective muscular contraction becomes evident. When the posterior muscles of the neck and back are paralyzed this important sign disappears. Kernig's sign is not, as a rule, present.

11. Spinal Fluid. The early pathological findings include congestion of the vessels of the meninges and a perivascular cell prolifera-

tion. The earlier clinical findings include stiffness of the neck and back and a moderate degree of retraction. In these early stages of the disease there is a meningitis. As might be expected, then, there are changes in the spinal fluid. Although the changes are not characteristic of this disease alone, lumbar puncture and examination of the spinal fluid are helpful in the diagnosis from many other conditions that show similar early signs and symptoms, and also in differentiating the disease from other types of meningitis. The fluid, though apparently increased in quantity, is not, as a rule, at greatly increased pressure, but may occasionally spurt out as in tuberculous meningitis. A slight opalescence and occasional flakes of fibrin have been described. The cells are increased in number, and there is an increase in the globulin content. Cell counts of over 1000 per c.mm. are found but they are rare, and counts of under 100 are more common. During the first few days polymorphonuclear cells and cells with irregular nuclei may be numerous, but after the first week the increase is due almost entirely to cells of the lymphocytic type. The globulin increase is found in half the fluids examined during the first week, and the proportion showing this abnormality increases to the third week.

In the first week after the appearance of the first symptom, nearly all the fluids show abnormalities in cell count, of globulin content, or both; in the fourth week about 50% are abnormal; and after the fourth week the proportion falls off very rapidly. The fluid does not clot and is sterile, and no organisms can be found in the centrifuged deposit. The changes in the spinal fluid seem to be independent of the onset of paralysis.<sup>2,4</sup>

III. Blood. The examination of the blood does not help to a positive diagnosis, as there is no change in the number of red cells, while the number of white cells is within the limits of normal variations. A slight increase in the proportion of polymorphonuclear cells may be seen with similar diminution in the number of lymphocytes.<sup>4</sup> A blood count is of value in that any great departure from the normal would indicate a search for some cause other than poliomyelitis.

IV. Disturbances of Motor System. After a variable period of preparalytic symptoms, paralysis is seen, and the diagnosis is then greatly simplified. The pathological lesions may be very diffuse or may be localized. The paralysis may involve almost all the body musculature or may be limited to a muscle group or a muscle. The lesion may be severe, producing a permanent complete paralysis of the affected muscles, or may be mild, causing a partial paralysis or only a temporary weakness. A most thorough examination is, therefore, necessary, and the strength of every muscle must be tested. Changes may take place rapidly and in the course of a few minutes, and frequent examina-

tions may be necessary to establish a diagnosis and to determine the prognosis. The most characteristic lesion of the motor system is an involvement of the anterior horn cells, resulting in a flaccid paralysis of the corresponding muscles. The lesion may, however, be in the higher parts of the cord or in the brain. A spastic condition would then result, and this is frequently seen, though usually as a transient condition during the period of advancing paralysis. The centres in the medulla oblongata are also frequently involved, giving bulbar paralysis. The irregularity of the distribution of the muscles involved is very characteristic of the paralysis of poliomyelitis. Hemiplegias and paraplegias are not common, and simple monoplegias would probably be considerably rarer than statistics show if some instrumental method of examination of the other muscles of the body were employed.<sup>5</sup> Even with the crude clinical examinations so far employed all the muscle groups of a limb are seldom equally involved. Weakness of a muscle of the eyeball on one side or a slight ptosis are not infrequent, and involvement of the muscles of facial expression was found in a third of the cases in one series. Seldom are the facial muscles on both sides paralyzed, and it is usual to find either the upper or the lower parts of the facial musculature only involved. The tongue, the palate, and the pharyngeal muscles must also be examined. The muscles of the neck and back and of the abdominal wall are important, as supporting apparatus may be necessary to prevent deformities if these groups are involved. Of greatest consequence to the patient is the condition of the respiratory muscles. Fatal cases invariably result from paralysis of the respiratory muscles. With the diaphragm alone, or with the serratus muscles alone, the respiratory movements may be carried out efficiently, but when both are paralyzed death results. From the first sign of weakness the spread to paralysis of both groups is sometimes very rapid, so that a careful examination is of the greatest importance. An estimate of the efficiency of the serratus muscles may be obtained by interfering with movements of the diaphragm by firm pressure on the abdomen, and of the diaphragm by the prevention of the expansion of the thorax by pressure there. Incontinence and retention of urine are both seen, and a flaccid condition of the anal sphincter is reported. Much information as to the condition of muscles can be gained from an inspection of the attitude of the patients as a whole, and of the limbs and by testing the tone of the muscles on passive movements. Isolated active movements are difficult to elicit in infants, and the coöperation of the mother is of the utmost value in completing a systematic examination.

V. Disturbances of Reflexes. Short of demonstrable disturbances in the functions of the muscles, disturbances in the deep reflexes are

found. In the early stages and in mild cases these may be the only indications of lesions of the motor mechanism, so that a careful examination of the reflexes is helpful. As in the case of actual paralysis, it is the asymmetry of the disturbances that is characteristic. Reflexes may be exaggerated one day and absent the next, with demonstrable paralysis not appearing until the day following; or, the reflexes may gradually be lost without any demonstrable paralysis whatever developing. Exaggerated reflexes in one part and absent reflexes in another may be present at the same time. Valuable information may also be obtained by the examination of the superficial reflexes.

VI. Disturbances of the Sensory System. It has been demonstrated that the earliest and most constant lesion in the experimental disease is found in the posterior root ganglia.<sup>6</sup> These rarely go on to complete destruction of the ganglion cells, so that, although permanent disturbances of sensation are not to be invariably expected, temporary disturbances during the stages of congestion and edema and cell infiltration may be expected. These interstitial changes have been seen in the preparalytic stages in monkeys. The pain and hyperesthesia may be due to these histological changes. Because of the usual age of the patients and their general condition in the acute stages, an accurate examination of sensations is impracticable by the ordinary clinical methods. Definite impairment of sensation has been demonstrated in a few instances in older patients. It is possible that many of the cases that have been called "abortive" would show changes if more accurate methods of estimating muscle power and sensations were available. It is probable that many cases of doubtful diagnosis could be cleared up by such examinations.

*Abortive Cases.* It is difficult for medical men who have not had opportunities to observe acute epidemic cases of poliomyelitis, to believe in the presence of abortive forms. It was first pointed out by Wickman<sup>7</sup> that abortive cases form a large proportion of all cases in an epidemic, and it has been suggested that they may even outnumber the paralyzed cases. It is of importance then, in taking any steps to prevent spread by quarantine, that the mild and abortive cases be recognized. The evidence in support of the occurrence of such cases is considerable, but owing to the nature of the condition it has not been possible to demonstrate the characteristic pathological lesions in a human case. The occurrence of every grade of severity, from the totally paralyzed rapidly fatal cases to the rapidly recovering cases, with at no time more than the mildest degree of weakness in one muscle, suggests that still milder cases, with general or perhaps meningeal symptoms only, must also occur. In most epidemics that have been carefully observed it has been pointed out that mild degrees of fever

and gastro-intestinal disturbances occurred to a greater extent than usual among the unaffected members of the community. In 1894 Dr. C. S. Caverly<sup>8</sup> noted that during the epidemic of that year in Vermont, the infectious diseases of children were accompanied by nervous disturbances. Kling, Wernsted and Petersen<sup>9</sup> demonstrated the presence of the virus of poliomyelitis in the throat washings of such cases. Changes typical of poliomyelitis have been demonstrated in the spinal fluid of such cases. Monkeys have been inoculated with small doses of the virus of poliomyelitis, and after showing the prodromal symptoms, have recovered, and their immunity demonstrated by their resistance to a second inoculation.<sup>10</sup> Such cases are characterized by the preparalytic and general symptoms described above. They are usually mild and ambulant, but may show the pain and hyperesthesia and meningitic symptoms. If such a condition is suspected, lumbar puncture should be performed.

*Diagnosis.* In the preparalytic period and in abortive cases the diagnosis depends, to a great extent, on the presence of an epidemic and association with other cases. Under these circumstances, a history of sudden onset with fever, gastro-intestinal symptoms and perhaps pain, would indicate a careful examination for signs of stiffness of the neck and back. If any suspicion of a meningitic lesion is entertained, lumbar puncture must be performed, when the condition of the spinal fluid will clear the diagnosis in most cases. The differentiation from a gastro-intestinal upset is most difficult. The onset may be quite sudden, the fever and general condition identical, and there is frequently objection to being handled and to flexion of neck and back. The spinal fluid is, however, normal; diarrhea is more usual than constipation, and the vomiting more persistent. The other common infectious diseases commence similarly, but in them the pain and hyperesthesia is usually absent, the spinal fluid is probably normal, and a characteristic rash develops. Sufficient data on the spinal fluid in acute infectious diseases have not yet been collected for the findings to warrant an absolute opinion. Skin lesions have been described, but are not constant in character and are present in only a small number of cases. Acute rickets is easily mistaken because of the fever, the prostration and the tenderness. The spinal fluid, however, is negative, and in poliomyelitis pronounced enlargement of the liver is not found. Tuberculosis of the hip can be differentiated by the history of onset. Acute rheumatic arthritis may commence acutely and the fever, pain and disinclination to move be very similar, but the tenderness is localized to the articular structures, and in poliomyelitis there is no swelling of the periarticular structures and no synovial effusion. Meningitis due to the meningococcus, to the pneumococcus, to the influenza bacillus,

to streptococci and staphylococci give a spinal fluid with cell increase due to polymorphonuclears, and the causal organism can be found in smears and can be cultivated. In tuberculous meningitis and syphilitic meningomyelitis the spinal fluid is very similar to that of poliomyelitis, and the clinical findings do not differentiate until the case has been watched for a few days. In tuberculous meningitis the bacillus can be found by repeated careful examinations, and in syphilitic meningitis the spinal fluid gives a positive Wassermann reaction. A positive Wassermann reaction in the blood is not sufficient to differentiate, as it may be found in acute poliomyelitis as in other acute infections. Even when evidence of paralysis or of involvement of the motor system is found, the diagnosis may not be clear. Tuberculous meningitis and syphilitic meningomyelitis require as careful differentiation in the preparalytic period. Evidence of tuberculous in other parts of the body and the absence of complete paralysis of muscle groups in a seriously ill child help to differentiate in the one case, and the signs of congenital syphilis in the development of the skeleton and the enlargement of the liver and spleen help in the other. Acute poliomyelitis is probably more often mistaken for cerebrospinal meningitis than for any other disease, especially as paralysis may occur in both, but the rash, the photophobia and characters of the spinal fluid should easily differentiate them. Brain tumors, tumors of the spinal cord, and many other conditions of the cerebrospinal axis have rarely to be differentiated. If physicians are alert and neglect no methods of examination that may help to a diagnosis, the abortive cases will be missed less often, and the frank cases will be recognized earlier and valuable help rendered in any attempts at prophylaxis by quarantine methods.

## ANATOMIC FORM AND POSTURE, IMPORTANT FACTORS IN THE TREATMENT OF PULMONARY TUBERCULOSIS.\*

By JOEL E. GOLDTHWAIT, M.D., BOSTON.

IN that which is presented to you tonight it is my hope that lines of investigation may be suggested that will be of help in understanding the conditions which lead to tuberculosis, with the natural effect which such understanding should have upon the control of the disease. That my remarks are made with much hesitation is not strange, in the light of the admirable work of the men of this community, added to the fact that the treatment of this disease, apart from its manifestations in the bones and joints, has received but little attention from me. My reason for venturing to speak to you is that in my twenty-five years of work with the chronic patient, a little of the wonderful spirit of optimism which your great leader, Dr. Trudeau, so largely possessed, has come through to me, resulting in the belief that all of these chronic diseases must be understandable by, and ultimately controllable through, the human intelligence. In the study which this spirit has forced, certain things have been revealed which have not only benefited the patients who turn to me for advice, but which seem of equal applicability in many other forms of disease. With the hope that some of these principles may be of benefit in your work, in pulmonary disease, I am venturing to address you.

In the first place, in attempting to fathom the nature of the chronic diseases it has been clearly shown that, despite the text-book teaching, human beings are not all made alike. That there are distinct types, showing differences in contour of body, form of skeleton, texture of muscle, shape and attachment of viscera, etc., etc., there can be little question, and all of this has been fully described in the Shattuck Lecture.<sup>†</sup> Not only do these types of anatomic form exist, but apparently each type has its own more or less definite potential of disease, and of these types the one which most concerns us, because tuberculosis is a part of its pathologic potential, is the slender type, which has been designated by different writers as the congenital visceropetetic, the carnivorous, the hyper-onto-morph.

Why this type is so commonly tuberculous is not, of course, wholly plain, but there are certain suggestive features. In the first place, the individual is usually poorly nourished, due perhaps in part to the fact that the length of the small intestine, from which the food must be assimilated, is much less than the normal, frequently not more than half. The blood pressure is usually considerably below what is con-

\* Address delivered before the Saranac Lake Medical Society, at Saranac Lake, New York, Feb. 9, 1916.

† An Anatomic and Mechanistic Conception of Disease, BOSTON MED. AND SURG. JOUR., June 17, 1915.

sidered normal, suggesting, as does the poor nutrition, a low resistance. There is usually more or less anemia. The internal glandular secretions are frequently disturbed, as well as other evidence of abnormal physiology.

To recognize these disturbances of physiology, however, does not necessarily explain their cause, and in the attempt really to get back to the primal reasons the following facts were revealed.

The slender anatomic type, if it develops naturally, acquires habits of carriage in the periods of rapid growth, in which the ribs are lowered and the chest is used in the position of full expiration. In this position the thoracic breathing must be very imperfect, and full expansion of the chest rarely occurs. Under such restriction the lungs cannot develop their full strength. In normal breathing there should be a moderate excursion of the chest, with the rise and fall just about midway between full inspiration and full expiration. The average ratio is one and one-half to two inches above the neutral to full inspiration, with about the same below the neutral to full expiration. In the posture naturally assumed by the slender anatomic type (when standing), the neutral position is, however, from one-quarter to one-half inch above full expiration, with an excursion of from two and one-half to three and one-half inches

above this point in full inspiration. Naturally this position of full inspiration is rarely taken.

In this position, with the lowering of the ribs or the flattening of the chest, there are two distinct types. In one the lateral diameter of the thorax remains the same and the front wall of the chest simply drops downward (Fig. 1), exactly as if a hoop attached at the back were lowered in front. Since the anterior part of the rib normally is lower than the attachment at the spine, the lowering of the anterior part below this normal must naturally lessen the depth of the chest,—its anteroposterior diameter.

In the other type the ribs are narrowed in at the side, with the result that the lateral diameter is less (Fig. 2), but with the crowding in

FIG. 1.—A case of pulmonary tuberculosis, in the slender anatomic type, with the chest flattened so that the antero-posterior diameter is less than normal. The lateral diameter is not changed.

FIG. 2.—The slender anatomic type with the lateral diameter much below normal, but with the antero-posterior diameter increased.

of the ribs from the side, the sternum must be forced forward, so that the anteroposterior diameter is usually above normal (Fig. 3). In this type of posture the lower ribs are drawn in so much that the angle formed by the edge of the lower ribs and the tip of the sternum is small and much less than the right angle, which is normal and which may exist in the other type of chest.

In the first type (Fig. 1), the chest is so much flattened that there must be less than the normal space for the heart, while in the latter (Fig. 3) this space is not as much interfered with. It is not impossible that this is one of the explanations for the rapid rate of the heart in some of the flat-chested individuals.

With the lowering of the chest to the position of full expiration, irrespective of whether the

sternum is flattened or forced forward, not only is the thoracic part of the respiration interfered with, but the position of the diaphragm must be

FIG. 3.—A tuberculous patient, showing the slender anatomic type, with the anteroposterior diameter greater than normal, due to the pushing of the sternum forward by the narrowing in of the ribs from the side.

changed, with resulting interference with its function. In normal breathing the movement of the diaphragm should be midway between full inspiration and full expiration (Fig. 4). With the posture here described, however (with the patient standing), the diaphragm is used

FIG. 4.—The photoscopic tracings of the diaphragm with the outlines of the heart taken of a person of the normal type of anatomy when standing. The two middle lines represent the excursion of the diaphragm in normal breathing. The uppermost line represents the position of the diaphragm assumed in full expiration, and the lowest line the position assumed in full inspiration. Note in this that the normal breathing should be just about midway between the two extremes. This condition is never seen in the slender or tuberculous type when the patient is standing.

at its low point or at full inspiration (Fig. 5), the upper point, or full expiration, being reached only when effort is made. This means

FIG. 5.—The photoscopic tracings of a patient of the slender anatomic type taken with the patient standing. The two middle lines represent the excursion of the diaphragm in normal respiration. The lowest line is the position of extreme inspiration, and the upper line the position of extreme expiration. It will be seen from this that in the slender type the excursion of the diaphragm is slight and only under considerable effort is anything like the normal excursion of the diaphragm made. When lying down flat upon the back and without pillows under the head, the diaphragm in this case at once assumed the position and the range of motion as shown in Fig. 4.

that this part of the respiratory mechanism must be seriously interfered with. From this not only must the lungs suffer, but from the appearance of the tracings it is probable that the heart action is also interfered with. Still further, this absence of the movement of the diaphragm must seriously interfere with the circulation in the abdominal organs, as well as interfering with their position and general function.

In the posture here described not only is the thorax changed in size, but with the lowering of the ribs there must be a narrowing of the space in the upper abdomen under the diaphragm. The result of this is that the proper amount of space in which the organs should lie does not exist, and because of this the organs must be forced downward, with undoubtedly more or less interference with the function of the organ displaced or of some of the other organs against which the displaced organs may be forced. With this crowding of the organs downward, the pads of fat which normally exist in the back of the upper part of the abdomen, are absorbed, and this absence of fat must expose the sympathetic ganglia in the upper abdomen, as well as such organs as the adrenals, the pancreas, the great blood vessels, etc., to injury or irritation. Just what this does to the physiology is probably subject to considerable variation and must be a matter of speculation; but since the respiratory function, as well as the circulatory, nutritive, and all of the involuntary functions of the body, are controlled by the sympathetic system, one cannot help questioning whether some of the symptoms which are seen in these cases are not to be explained by this mechanical stimulation or inhibition of these

ganglia. It is not our purpose to go into all the possible suggestive evidence in this line, more than to call attention to it and to state that apparently vigorous health does not occur until, with the general remodelling of the body, these fat pads are replaced.

That which has been stated thus far assumes that the body is studied in the standing position. Under these conditions the lungs cannot work rightly because of the change in the shape as well as the movement of the thorax, and also because of the change in the position, as well as in the movement of the diaphragm. This naturally results in the lungs being weaker and less resistant than is normal. Added to this, the disturbance of nutrition, with the possible disturbance to the physiology resulting from the irritation of the abdominal ganglia, and the conditions seem to be reasonably favorable for the development of disease, whenever the pathologic organism is introduced.

While all this is true if the body is considered when erect, it should also be remembered that other postures may be even more harmful. The relaxed or slouched position so commonly seen in sitting, or the more or less common bedtime position, with the head and shoulders raised upon two or three pillows (Fig. 6) may restrict

FIG. 6.—Not an uncommon position for patients to assume while in bed. The effect which such position must have upon the breathing or upon the function of the abdominal organs must be obvious.

the thoracic or diaphragmatic function even more than has been described. The position of the diaphragm under these conditions is crowded upward to the position of full expiration (Fig. 7), with very slight range of motion in breathing, while at the same time the position of the thorax is changed but little. This naturally increases the restriction of the breathing, and since, as is shown by the tracings, the heart at the same time is crowded upward into a more confined space, it is not impossible that some of the symptoms of disturbed circulation and thoracic distress may be due to this.

To understand the types of posture here shown, and to appreciate that which is naturally involved in the treatment, it should be remem-

bered that the suspensory ligament of the diaphragm is the pericardium, with the expansion at the top into the fascia that is attached to the sides of the low cervical spine (Figs. 8 and 9).

FIG. 7.—Fluoroscopic tracings of the diaphragm and the outlines of the heart taken with the patient lying down and with two pillows under the head. The two middle lines represent the excursion of the diaphragm in natural breathing. The upper line is the position of extreme expiration, and the lower line the position of full inspiration. From this it is seen that not only is the diaphragm raised and moves but little in ordinary respiration, but that it is forced up to the position of almost full expiration.

FIG. 8.—Showing the relation of pericardium to diaphragm with the extension of the fibres of the pericardium into the fibrous bands which are attached along the sides of the low cervical spine forming the suspensory ligament of the diaphragm.—*Archiv. f. Anat. u. Physiol.*, 1877, Taf. xv.

Drag upon this will result in the cervical spine being bent forward and the ribs lowered, as is shown in Figs. 1 and 3.

To raise the diaphragm and to elevate the

ribs, the cervical spine must be flattened as it is when the head is fully erect, and if this connection between the low cervical spine and the diaphragm is not appreciated, it can easily be demonstrated by standing with the body relaxed and drawing back the head, as if making a "double chin." One cannot do this without raising the ribs and drawing in the upper abdomen.

FIG. 9. Lateral view showing effect of the pericardium upon the diaphragm as the suspensory ligament with the fibrous bands extending up to the sides of the low cervical spine.—*Archiv f. Anat. u. Physiol.*, 1877, Taf. XI.

Of interest in this connection are the reflex acts of sighing and yawning. Both are, when analyzed, movements of the diaphragm toward full inspiration, and are made usually when one is sitting slouched or when pillowed up on couch or bed. The sigh or yawn is apparently to overcome the harmful effect of these postures. To sigh with the head forward and the chest relaxed is possible but not natural, while to yawn with the head and chest in this position is impossible. To yawn, the head must be raised, the upper spine straightened, and as a part of this the ribs and diaphragm are raised. Whether these instinctive acts are performed to relieve thoracic or abdominal discomfort, is not always plain, but that it must be partly thoracic there can be little question.

The practical suggestions which these facts have for us are, it seems to me, that if we are to do the best we can to ensure health, with the greatest amount of vigor to combat disease of

any kind, we must see that the body is so used that the rhythm of respiration, both as it refers to the thoracic and the diaphragmatic movement, is as nearly normal as possible. This is obtainable only when the body is used without being bent at the waistline or drooped. In sitting or standing the torso should be straight, as it would be if fully erect, and in lying down the same straight position without pillows should be insisted upon.

These positions not only ensure a better chance for the proper development of the lungs, but the abdominal organs must be drawn into better position, so that their function must improve also.

To use a back brace for a case of pulmonary tuberculosis may be unusual treatment, but with these facts before us it is not irrational, and both of the cases depicted in Figs. 1 and 3 were referred to me by men trained, as you are, in pulmonary disease, with the request that I do what I could by remodelling the body so that the lungs could have a proper chance to regain their strength, and thus arrest the disease. Since in both of these cases the disease was active at the time the orthopedic treatment was started, special gymnastic work could not be undertaken in the beginning, and braces which held the body erect and the chest raised, had to be used until the lungs had so far recovered that active exercise was possible, these braces being discarded as soon as the muscles had gained sufficient strength. Our aim should be to make the full excursion of the chest in inspiration and expiration possible with the least effort. Much emphasis is put upon giving such patients plenty of fresh air, but it must be obvious that the air cannot get into the lungs in any considerable amount if the chest is allowed to remain, as is shown in Figs. 1, 3 and 6.

The importance of the posture should be borne in mind at all times, and particularly as the patients are put out in the open to "get the

FIG. 10.—A more or less typical attitude, to be seen on the piazzas of our tuberculosis sanatoria, in which the breathing must be seriously interfered with, and which can easily be prevented by care in arranging pillows, stiffening the back of the seat, etc.

FIG. 11.—The same as Fig. 10, except that a board is placed on top of the canvas under the back of the patient. While this position is not ideal, the torso is relatively straight and the breathing comparatively little interfered with.

air." If propped up in bed, as in Fig. 6, obviously but little air can get inside the individual, and this is also true if some of the reclining chairs which are used at our sanatoria, especially the canvas steamer chair (Fig. 10) are allowed. The positions assumed in many of these must result in an increase in the mechanical difficulty under which the patient labors, with harm to the lung tissue rather than benefit. If such chairs must be used, the harmful features should be appreciated and corrected. With the canvas steamer chair the simple use of a board at the back placed on the canvas makes the chair much less objectionable (Fig. 11). If the bed

FIG. 12.—Half reclining position with pillows so placed that the torso of the body is relatively straight. To make this possible a large pillow under the knees to flex the thighs is necessary. The breathing in this position would be but little, if any, interfered with.

position is to be used, naturally the position of Fig. 12 is better from the point of view of thoracic function than Fig. 6.

If these things are recognized and the harmful features are prevented by training in childhood, at which time the types can be easily recognized (Fig. 13), it seems not improbable that

FIG. 13.—The slender congenital visceroptotic type as seen in childhood, showing at this early stage the same characteristic attitude with the flattened chest as is seen in the adult. This is the tuberculum type.

there will be less tuberculosis, because the vitality of the individuals of this type will be greater, and that when it does occur, its control will be more easy.

## THE TEACHING OF THERAPEUTICS AS A BRANCH OF APPLIED PHYSIOLOGY.\*

BY F. H. McCrudden, M.D., S.B., BOSTON.

*Laboratory Director, Robert Brigham Hospital, Boston; Assistant Professor of Applied Therapeutics, Tufts Medical School.*

THE teaching of therapeutics is one of the weakest points in the training of the medical student. The actual details of treatment are taught incidentally to the other instruction in clinical medicine; and as the basis for such instruction the student is given a course in pharmacology dealing with the properties and action of drugs. But no systematic instruction is usually given in the *general principles* of therapeutics. The clinician says the course in pharmacology is not practical enough; the pharmacologist says the clinical instruction in therapeutics is not scientific. Both criticisms are wrong; so far as it goes, the instruction in

\* Part of an address read at the joint session of the Association of American Medical Colleges and the Federation of State Medical Boards, Chicago, Ill., Feb. 8, 1916.

therapeutics in both of these courses is usually good; but it is incomplete.

In the course in clinical medicine the attention of the student is directed chiefly to symptomatology and diagnosis; treatment is relegated to a subordinate position with the emphasis on the details. This emphasis on the details is correct enough in such a course. A disease may take such variable forms in different persons, and change so much from day to day in any one person that the treatment of every new patient is a new problem. In chronic diseases especially, where the exact details of treatment depend largely on the severity of the disease, on the extent to which function is disturbed, on the condition of the patient as a whole—factors concerning which exact measurements play as yet but a small part, and for which judgment is gained only by long clinical experience with cases of all grades of severity—we treat individuals rather than diseases. The details of treatment can, therefore, be learned only by the inductive method—long-continued bedside observation of many patients under treatment—now used in teaching the subject. But back of the many details there are certain general principles which can be discussed deductively.

Pharmacology deals with only a part of these principles, and then not from the standpoint of therapeutics. It deals with the physiological action of substances, independently of their therapeutic effect; with the action not only of therapeutically useful substances, but also others—muscarin, curarin, and saponin, for example—whose action is chiefly harmful; and in the case of useful drugs, not only with the therapeutically important activities, but also those of no therapeutic significance. Pharmacology has developed to such an extent that it is now pursued as an independent science without reference to the practical needs of medicine in the same way, and with the same justification that anatomy, physiology, and chemistry—once a part of practical medicine—are now pursued as independent sciences; and books are written on pharmacology, instruction is given in the subject, and research is carried on by men who are not physicians. In actual practice drug treatment is combined with other forms of treatment—light, heat, cold, exercise, posture, diet, massage, electricity, x-rays, and high altitude—an intelligent application of which depends on a knowledge of physiology, physics, chemistry, psychology, and other factors—the personality of the physician even—as well as pharmacology. A knowledge of pathology and clinical medicine especially, though not necessary for the pharmacologist, is an absolutely necessary prerequisite for the study of therapeutics; the therapeutically important questions relating to the effect of pathological conditions in altering the effect of drug action and to diagnosis and prognosis, which have to

be taken into consideration in deciding when and how to use drugs in disease, are outside the province of pharmacology.

A division of medical science dealing with the aims and methods of therapeutics and filling in the gap between physiology, chemistry, physics, pharmacology, and the other fundamental sciences which underlie the methods of treatment, on the one hand, and the actual details of treating individual patients from day to day, on the other, should be recognized; and a course in this subject should be added to the medical curriculum. The instruction should aim to give the student a point of view regarding these purposes and principles of treatment, so that these details may be contemplated, not as a vast number of empirical, and unrelated elements, but as mutually dependent parts of a whole; it should continue the emphasis on scientific habits of thought, which is one of the objects of instruction in physiology and the other fundamental branches of medical science, and bring out the fact that *therapeutics is not an empirical art, but an applied science.*

It is very important, too, to impress students early in their medical career with an optimistic and hopeful attitude toward the results of treatment. Since it is only through feeling confident of obtaining good results that the physician can carry out his treatment with enthusiasm, great attention should be paid to demonstrating that, under proper treatment, chronic disease has a hopeful outlook. Our optimism at the hospital, where my own course is given, is due not alone to the adoption of the physiological point of view regarding the purpose and principles of treatment, but also, in part, to the fact that we see the results of treatment *with the treatment properly carried out.* The less optimistic attitude of many physicians is due, not to the poor results of treatment, but to discouragement *at the difficulties of having treatment intelligently carried out in private practice*—a distinction that should be brought home to the student.

For an understanding of rational therapeutics a study of the treatment of chronic disease forms the best basis. As contrasted with the general supportive treatment of acute infectious disease, the treatment of chronic disease usually centers around improvement in the efficiency of some one organ or function; discussion and demonstration of treatment is, therefore, simpler. Changes due to the disease itself are less rapid than in acute disease, so that the effect of the treatment is more clearly discernible. The long duration of the disease makes possible a comparison of different forms of treatment in the same patient.

The treatment of chronic disease is very important. Only a small portion of the population suffers from acute disease at any one time; and the illness lasts but a short time—within a few weeks the patient is either well or dead.

But a large proportion of persons who have reached middle life suffer from some weakness of function, some handicap based on a physical defect—in its broadest sense some form of chronic disease; to adjust such persons to their handicapped condition, and thereby to maintain efficiency and comfort and to prolong life may require more or less constant medical attention.

The treatment of chronic disease is difficult. Compared with some of the clear indications for treatment in acute infectious disease—indications for diphtheria antitoxin, or for appendectomy, for example—the indications for treatment in chronic disease are lacking in precision. The severity of the disease, the degree to which functional efficiency is impaired—factors which determine the details of treatment—cannot usually be accurately measured; their estimation is subject to great errors of judgment; and estimations of the effect of treatment on such factors—on the degree of dyspnea, cyanosis, weakness on exertion in heart disease, for example—require not only skill and experience, but a certain amount of natural ability and aptitude. In the treatment of chronic disease, moreover, a broader view of all the circumstances of the case must be taken than in acute disease: facts concerning the patient's occupation and the state of the family and financial affairs may influence the treatment; for the few days during which they are sick, no matter what may be their family or financial responsibilities, all patients with such diseases as pneumonia or scarlet fever usually succeed in obtaining the same excellent treatment.

It may be objected that in presenting principles of treatment to students before they know much about the details of treatment, I am committing the very grave error of placing abstract ideas before concrete examples. The objection may be raised, too, that the subject of the purposes and principles of therapeutics is one of great controversy, that different physicians have different points of view.

As to the first objection: It is, of course, true that empirical experience should precede scientific conception; that educational advance should proceed from the concrete to the abstract. But this cannot be used as an objection to a course such as I have outlined; for I have discussed here only the *subject matter* of the course, not the *method of presentation*; in presenting the subject matter the instruction can be, and should be based upon and proceed from concrete examples of treatment.\*

As to the controversies: The principles as laid down should not be taught as rigidly crystallized doctrine; the purpose should be not to inculcate dogma, but to enlighten the understanding and to stimulate the use of the intelligence in the application of treatment. Scientific education should consist not so much in the accumulation of facts, as in the development

of scientific habits of thought; in the cultivation of correct points of view; in the establishment of a state of mind in which the facts can take their proper place. Some of the details of treatment, as laid down, may be of doubtful value, details that research is constantly modifying; so, too, elements of even greater moment, some tenets of the principles of treatment as stated, may exhibit faults and inconsistencies, or a distorted perspective in the emphasis laid on different parts. This is unavoidable. The details and facts must be used as the stuff out of which the ideas are formed; but they should not be taken for the idea itself. The physiological point of view regarding the purpose and principles of treatment\* may be compared with a wave; though the actual physical particles of which the wave is composed change from instant to instant, the wave maintains its form and character. It may be compared with life itself—with a unicellular ameba, for example; the ameba is continuously changing its form, and the particles of which it is composed are constantly changing; but the living essence, the cell itself, remains. Under the influence of a correct point of view, facts arrange themselves in order, like iron filings under the influence of a magnet. The physiological point of view serves to bring system out of chaos; a statement of the facts of therapeutics, subordinated to certain guiding ideas, is to the disordered array of unrelated "remedies" and prescriptions, which the student commonly accumulates, what a disciplined army is to a mob of individuals. The point of view is simple, definite, and clear; and it is elastic enough to respond to the necessity of incorporating newly discovered elements of treatment. The chief guides in determining what principles to lay down should be *usefulness and elasticity*; the test of usefulness to restrain any tendency toward barren abstraction; that of elasticity to avoid the other extreme of fixed and rigid canon. As details become obsolete they can be replaced by better ones; but even though large parts of the scheme of treatment have to be altered to conform to the results of scientific progress, the idea itself—like the ameba or wave mentioned in comparison—will still remain as a paradigm.

Since students take up the study of medicine for the purpose of learning to treat sick patients, such a course as that which I have outlined should be the most important in the curriculum. The practical purpose of courses in pathology, physiology, diagnosis, and the other fundamental branches is to help in understanding the treatment of patients; and the details of therapeutics as demonstrated in the subsequent clinical courses are merely illustrations of the practical application of the principles of therapeutics.

\* For the details of such a course see my paper in the BOSTON MEDICAL AND SURGICAL JOURNAL, Vol. cxxiii, p. 574, 1915.

## Clinical Department.

### EXFOLIATIVE DERMATITIS FOLLOWING NEOSALVARSAN INJECTIONS.\*

BY RENÉ BINE, M.D., SAN FRANCISCO, CAL.

SOON after the introduction of salvarsan and neosalvarsan in our therapeutic armamentarium, skin manifestations following their administration attracted considerable attention. Various degrees of erythema and dermatitis occurred with great frequency, but usually of such a degree, and of such short duration, as to arouse scientific interest rather than uneasiness. Many of these eruptions were found to be due to so-called "Wasserfehlern,"<sup>1</sup> while others were attributed to patients' idiosyncrasies.

Genierich<sup>2</sup> states that other symptoms indicating hypersensitiveness to salvarsan, usually precede the severe skin lesions. He reports one case where these warnings being disregarded, severe toxic reactions, including a generalized dermatitis, resulted.

Swift's case,<sup>3</sup> a patient with leukoplakia, developed a severe vesicular dermatitis after his eighth treatment. He then was without treatment for eight months, at the end of which time a single intravenous injection of 0.3 gm. was accompanied by a sensation of pressure in the chest, followed in four hours by a generalized erythematous eruption which later became vesicular. Swift considered such reactions as due to anaphylaxis. They appeared only after repeated injections.

Genierich<sup>2</sup> states that icterus is most apt to occur if one exceeds eight injections, or an amount of 4 gms. during an intensive cure. In addition to other toxic effects, the liver may be swollen and tender, the stools acholuric; the patient usually suffers from dyspepsia. Recovery occurs within three or four weeks.

Stulmer<sup>4</sup> states that exanthemata following salvarsan usually appear after seven to twelve days, and that skin reactions were most often seen in those cases where the second or third dose came on the seventh or eighth day. He found that as soon as the eruption had disappeared, he could safely continue the treatment.

Kersten<sup>5</sup> reports a case of a Japanese prostitute, age 20, who because of a chancre, received 0.6 gm. 914 intramuscularly on Aug. 6, 1914. A second similar dose on Aug. 10, 1914. That night 39 C; felt ill, nausea. Inside of two days eruption involving mucous membranes, with edema of face. Skin soon became bluish in color, and later covered with vesicles. Mentality clouded. Inside of a week, practically well.

Wechselmann<sup>6</sup> believes that many of the eruptions attributed to salvarsan poisoning may be really due to the mercurial medication employed in most reported cases. On the other hand,

A. Neisser has shown quite conclusively that severe, universal, exfoliative and ezeematous erythemas may follow the use of salvarsan in cases where no mercury was ever prescribed.

Spence's<sup>7</sup> case presents such points of interest as to warrant an extensive report.

Male patient, age 25, contracted syphilis early in August, 1914, but had no treatment until October 31st, when he appeared with well developed secondaries, including a profuse maculopapular rash and mucous membrane lesions. Six weekly intramuscular 40% grey oil injections. Three weeks later, i.e., Jan. 3rd, 1915, 0.6 gm. Billon intravenously. Severe headache next day. January 9, diffuse erythema. January 23rd, dermatitis with edema of face and extremities, pyrexia; consequently admitted to hospital where he remained nearly six months with a most pronounced and versatile general dermatitis, intense erysipeloid erythema being first associated with vesicles, blebs, pustules and impetiginous areas about the hands, nostrils and lips, and then a copious and prolonged desquamation. Concurrently developed severe nasopharyngeal inflammation, mucopurulent conjunctivitis, weakness, emaciation. Every vestige of hair, finger and toe-nails shed. No gastro-intestinal, renal or nerve involvement. Was home in bed for two months more. Ten months after injection, head still showed a few small patches of cicatricial alopecia and a great thinning of hair. Nails had all returned. Marked pigmentation and slight brawny desquamation still seen; moderate keratosis palms and soles.

In the discussion, following Spence's report, Mr. McDonagh said that he considered this case a typical instance of the form of arsenical poisoning seen on using French and English substitution products for "606" and "914." He had seen nine similar cases, two of which had ended fatally. In no case had more than two injections been given, and in some only one. In one case the dermatitis did not appear for nine weeks after the injection. Before the war he had seen only one case of exfoliative dermatitis following the use of salvarsan.

The following case, presenting many unusual features and questions of practical interest, is reported in detail.

Miss N., stenographer, age 19. First seen June 1st, 1915.

*Family History.* Mother died one year ago of some acute psychosis. Father living, quite nervous. One sister and one brother alive and well, also several maternal uncles and aunts. No syphilis in family so far as can be elicited.

*Past History.* Measles and chicken-pox in childhood. Pneumonia as a baby. No scarlet; no typhoid; no malaria.

*Present History.* February, 1915, an eruption appeared all over the body, including face. Felt perfectly well; had no fever, and if it were not that the eruption appeared on the face, would not have consulted a physician. The

\* Read before the San Francisco County Medical Society, April 4, 1916.

eruption was very intense; there was marked swelling of the lower extremities which were intensely red, and pitted on pressure. Had no sore throat. Dr. Y., the family physician, thought that she had scarlet fever, and kept her in bed one week, but the course of the disease obliged him to abandon this diagnosis. When the eruption had entirely disappeared, a Wassermann test was done; the report was ++.

Dr. Y., therefore, informed the patient that the rash was probably syphilitic, but that he was puzzled because of the absence of any primary sore, or possible source of infection. He prescribed mercury pills, of which she took twelve daily from that time up to the present date. In the meantime the patient's family physician died; on that account she consulted the writer. (Not wishing to worry her relatives, Dr. Y. and Miss X. kept them in ignorance of her disease.)

Physical examination revealed no abnormality; no skin lesions; no mucous patches; no anemia; no fever; no signs of involvement of organs of special sense; no bone or nerve lesions; no adenopathy; hymen intact; urine O.K.

**Diagnosis.** In the absence of any signs of syphilis and realizing that errors in Wassermann interpretations occur, as well as in view of the fact that scarlet fever at times gives a positive Wassermann reaction, we felt that it was absolutely necessary to repeat the test before proceeding with any treatment.<sup>8, 9</sup> The patient was informed that if the Wassermann test was reported negative, it would be necessary to repeat it at a later date, as she had, as before mentioned, taken considerable mercury.

June 8th, 1915. Wassermann was reported + + +. We were obliged to assume the correctness of Dr. Y.'s diagnosis, and to treat the patient accordingly. Because of her occupation, and of her desire to keep her illness secret, it was decided to give her mercury injections, and, as soon as her work would permit, to give her some injections of neosalvarsan.

June 15th, 1915. One c.c. of 10% mercury salicylate intramuscularly; this was followed by considerable abdominal pain.

June 28th, 1915. Mercacodol 2 c.c. intramuscularly.

July 6th, 1915. Neosalvarsan 0.9 intravenously; no after effects.

July 8th, 1915. Mercacodol 2½ c.c. intramuscularly.

July 12th, 1915. Neosalvarsan 0.9 intravenously.

July 13th, 1915. Patient phones that she had severe headache, otherwise happy and at work.

July 16th, 1915. Patient feels miserable, at times chilly, at times warm; feels bilious and thinks a physic would do her good. This morning noticed a slight eruption on her forearm. She had gone walking in the hills July 12, and had been exposed to poison ivy to which she was

subject; she thinks that this accounts for the eruption.

**Examination.** Hands are markedly tremulous. There is an eruption composed of small, reddish macules, on the flexor surface of both forearms. No eruption on rest of body. Temperature 101.8. Throat, negative.

**Treatment.** Aspirin 0.3, to be taken every four hours. A dose of salts to be taken immediately.

July 19th, 1915. Patient states that her eyes have been very much injected and reddened during the last few days, and that a marked eruption had appeared on her arms and legs. Eyes today are considerably better and the eruption has gone.

**Examination.** Except for very faint macular eruption on the arms, nothing found.

July 26th, 1915. Feeling perfectly well. Wants treatment continued.

**Treatment.** Mercury salicylate 10%, 1 c.c. intramuscularly.

August 8th, 1915. Patient complains of an itching eruption all over the body. She says that it is exactly the same sort of a rash as the one she had when she first consulted Dr. Y. Feels tired and depressed.

**Examination.** There is a scarlatiniform eruption over entire body, most marked, however, over arms and legs. Here, in spots, skin is infiltrated and raised. Conjunctivae edematous; face quite swollen and covered with eruption. Legs swollen; patient can hardly get into shoes. No swelling of mucous membrane of mouth. Urine negative.

**Treatment.** R. Salol 4.0; divide in pulv. No. 12. Sig: 1 every four hours. To remain in bed on milk diet.

August 12th, 1915. Patient does not feel at all ill, but the skin of face, as well as rest of body, so swollen as to disfigure her beyond recognition and deprive her of desire of even leaving room.

**Examination.** Diffuse erythematous eruption over the entire body; marked edema involving particularly the face, so that the eyes are almost closed. Legs markedly swollen and reddened, eruption here being definitely purpuric. Legs pit on pressure. Abdomen slightly distended; liver easily felt about 4 or 5 cms. below right costal margin; edge not tender. Spleen; moderately soft; easily palpable on deep inspiration. Temperature and pulse normal. Conjunctivae icteric. Skin has yellowish hue which can be recognized in spite of intense rash. Urine; traces of albumin; trace of bile; few hyaline casts. Stools; clay colored.

**Examination.** August 14th, 1915. Purpuric eruption covers legs. On close examination one can see minute hemorrhages in skin wherever involved. Eruption most marked over upper and lower extremities; trunk of scarlet red color, through which one can see yellowish tinge of jaundice. On neck are small spots, about the size of a nickel, where desquamation has begun.

On back of heel is a very large desquamating area. Slight but offensive yellowish oozing all over trunk and face. Considerable vaginal discharge.

August 16th, 1915. Marked desquamation over entire body; over posterior surface of legs, skin coming off in great big pieces. Jaundice still quite distinct. Stools a bit darker and urine lighter in color.

August 18th, 1915. Urine still contains bile. Stool markedly clay colored.

August 24th, 1915. Patient still worried about her condition, but outside of that feels perfectly well.

*Examination.* Still disfigured beyond recognition. Face swollen; eyes still closed, jaundice still present.

September 4th, 1915. Face is drying; oozing of yellowish serum is less, but skin is getting cracked, particularly around lips and eyes. Skin is under marked tension, so that the eyes are kept wide open, and patient has difficulty in seeing.

*Treatment.* Boracic ointment to be applied over face, in form of a mask. Also compound cathartic pills to be taken, one at bedtime.

September 28th, 1915. Hair has been coming out quite considerably.

*Examination.* Quite bald over front part of head; hair is very thin even over back of head. Arms great deal better but face still covered with scales; the legs still of a deep purple.

October 1st, 1915. Hair has all come out. Complaints of vaginal discharge. Smears made from latter show numerous pus cells and a few gram negative cocci and diplococci; no intracellular organisms.

January 11th, 1916. Hair has begun to grow; is about one inch to one and a half inches in length; and quite thick, but light in color. Face still somewhat puffy. Legs distinctly purpuric. Hard edge of spleen easily palpable.

March 20th, 1916. Wassermann: faintly positive.

1. What was the nature of the eruption, which led the patient to consult her physician? From her description, it must have been of a scarlatiniform type. Unfortunately the dead physician's records are not available. He told her, however that the original infection must have occurred a few weeks before the rash,—this in spite of the absence of signs of primary lesions. Late secondary syphilides are not unknown, but the intense cutaneous reaction, the deep color, and rapid evolution of the eruption are certainly against its having been luetic. The Wassermann reactions deserve consideration, especially as the first two were triple positive, the last one only being but faintly positive. Is the presence of a positive Wassermann, proof of an active syphilis demanding treatment? Have we reached a stage where we are to treat a positive Wassermann, or should we still confine our efforts to treating a patient, leaving otherwise clinically healthy persons alone. We

know how unreliable Wassermann reports may be. We nevertheless believe that in most instances an absolutely positive Wassermann reaction indicates the presence of living spirochetes in the organism, and that we are justified in diagnosing syphilis whether symptoms are or are not present, and whether there is or is not a history of infection.<sup>10</sup>

2. What caused the purpura, jaundice, big liver and big spleen which manifested themselves twelve days after an injection of mercury, twenty-seven days after a second dose of neosalvarsan? The neosalvarsan was given in two relatively large doses, at a six-day interval. In addition to a relative overdose, and even assuming a possible idiosyncrasy to the drug, could such reactions be due directly to neosalvarsan poisoning? (Spence's case is perhaps the only one on record, which can be at all compared to ours.)

The larger part of the injected drug reaches the liver, which is, therefore, subjected to its action. Of this action we know nothing except by clinical results, and we cannot explain why some injections are followed by light subicteric coloring of the conjunctivae and skin, others by well marked jaundice with symptoms from other organs as well. These conditions have, however, been observed, where relative or absolute overdoses have been injected, or where the liver itself was previously diseased, thus rendering it easily affected by small doses.<sup>11</sup>

In our cases we must conclude, that while the patient's original eruption may have been syphilitic, the weight of evidence is apparently against such a diagnosis, and rather suggests a general exfoliative dermatitis.

We certainly cannot consider the eruption a late manifestation of congenital lues, there being no signs of such trouble. To explain the positive Wassermann on this basis, does not seem justifiable, the family history apparently excluding this. The patient's brother was the only member, however, whose blood could be tested, and here the Wassermann was absolutely negative.

We must further conclude that while the skin lesions following the administration of the neosalvarsan may have been due to arsenic poisoning, they bore sufficient resemblance to the first eruption as to warrant assuming a common etiology. As to the nature of the latter, we do not feel justified in drawing conclusions.

## A REVIEW OF 127 CLINICAL CASES OF ATAXIC PARAPLEGIA.\*

By G. H. BIGELOW, BOSTON.

[From the Neurological Clinic, Massachusetts General Hospital.]

FROM 1903 to November, 1915, the out-patient records at the Massachusetts General Hospital show that the diagnosis "ataxic paraplegia" has been made 127 times. Of these, 70% were males, whereas in the whole Out Patient Department, approximately 58% are males.

In 83 cases we established a possible etiology, though some, perhaps, on rather meagre evidence. They were: syphilis 43, following accident 10, following acute infections 6 (diarrhea, grippe, rheumatic fever, typhoid, infectious arthritis, and meningitis), hemiplegia 5 (which suggested hypertension with possible hemorrhage, etc.), alcoholism 5, malformations or irregularities of the spine 3, hypertension (at time of examination) 3, chronic disease 2 (gout and sepsis), exhaustion 2, anemia, lead poisoning, neurotic family history, exposure, heredity, tumor and pellagra, each one. In 44 cases no possible etiology could be found.

Of the 43 syphilitic cases only 7 showed positive laboratory findings in the blood (3 cases), or spinal fluid (2 cases), or both (2 cases). Two were strongly positive, one moderately, and one weakly positive, while three were reported "positive" without any qualification. One case was considered positive in spite of negative laboratory findings because of the marked improvement with salvarsan. Eight gave a history of syphilis; 6 showed it clinically, that is, there were scars and pupils; 18 were syphilitic clinically and also by history; while 2 showed it clinically and therapeutically, i.e. improved under anti-specific treatment. One was diagnosed in the House, spinal syphilis in spite of negative laboratory findings on the basis of symptoms and irregular pupils. Thus it would seem that syphilis as an etiological factor in ataxic paraplegia is, of course, far less constant than in tabes, and when present is less frank, giving moderately positive or negative laboratory findings.

This is quite contrary to the statements in the literature. Gowers<sup>1</sup> says, "A history of syphilis is as rare in paraplegia as it is common in locomotor ataxia." Dana<sup>2</sup> agrees with this. Osler<sup>3</sup> denies the relationship to syphilis except in rare instances. Putnam<sup>4</sup> finds the indications

of syphilis exceedingly rare, if not wholly absent.

Here is the history in brief of one of the typical cases:

William S., age 36, seen first in October, 1903, complaining of weakness of the legs, of insidious onset, which the patient dates from a fall on the ice six years before. Feet feel as if walking on felt. Difficulty in walking in the dark. Severe frontal headaches for the past two months. Physical examination shows impaired muscle sense, otherwise negative. A year later unequal and irregular pupils were noted. In 1910 examinations showed increased knee-jerks, positive Babinski and clonus, urinary incontinence and a spastic gait. Dr. Baldwin notes that it is a typical case of spastic paraplegia. In 1914 two blood Wassermans were done and both were positive. Last November besides the signs mentioned above, he showed a positive Romberg. His ataxia was so great that he was forced to use crutches. There was subjective numbness as high as the crests of the ilia. Pain and temperature sense were normal, but light touch was impaired. The urinary incontinence had improved. His arms were unaffected. Before the days of the Wassermann this case would without doubt have been considered of traumatic origin.

The complaints given at the first visit were tabulated. Of the 127 cases, 112 or 88.3% complained of objective or subjective disturbances of the legs. Of the other 11.7%, the primary complaint was in some cases urinary disturbances, in others paresthesia or weakness of the arms, dizziness, headache, etc. It is because of this preponderance of leg complaints, undoubtedly, that 50% of the cases not admitted directly to the Nerve Room, were sent to the Orthopedic.

The predominant symptoms were also tabulated. Those showing principally spasticity were 52, ataxia 49, paresthesia 9, bladder symptoms 3, flaccidity 3. In 11 cases the notes were so meagre that it was impossible to determine.

The treatment was enormously varied. It included mercury, salvarsan, K I, Zander, electricity, massage, Fowler's solution, iron, brace, jacket, Thomas heel, advice, urotropin, and "stop lead." In each case the etiological factor, when discovered, was attacked; otherwise the treatment was symptomatic.

As to the course of the disease, only 71 cases returned often enough for any conclusions to be drawn. Of these 25 were better, 18 were worse, and 27 practically stationary. One patient was entirely cured, according to the record, but the notes are so meagre that the diagnosis may well be questioned.

In conclusion it seems from the analysis of these cases that syphilis is an important etiological factor in ataxic paraplegia.

## Book Reviews.

*Artificial Feeding of Infants. A Technique for the Calculating of Percentages and Values in the Artificial Feeding of Infants.* By MERRICK LINCOLN, M.D., Assistant Visiting Physician to Memorial Hospital, Worcester, Mass., assisted by GEORGE CHANDLER LINCOLN, M.D., Assistant Visiting Obstetrician to Memorial Hospital, Worcester, Mass. Worcester, Mass.: The Davis Press. 1916.

This little pamphlet, which can easily be carried in the waistcoat pocket, contains an immense amount of information culled from textbooks and periodicals. We know of no place in which so much has been collected in so small a space. It is truly a *multum in parvo*. It contains tables showing the analyses of milk and cream, the percentage requirements of babies of various ages, the composition of various foods, both non-proprietary and proprietary, as well as many others. It gives methods for the modification of milk and for the calculation of the caloric value and composition of food mixtures, as well as many other valuable data. It is intended, as the author states, rather for the pediatricist than for the beginner or the busy practitioner who wishes a short cut. It should prove of value, however, to everyone who will take a little trouble to become acquainted with the rudiments of infant feeding before he attempts to use it. Our only criticism is that the methods of calculation advocated seem to us unnecessarily long and complicated.

*Diseases of the Skin.* By HENRY H. HAZEN, A.B., M.D. Two hundred and thirty-three illustrations, including four color plates. St. Louis: C. V. Mosby Company. 1915.

Text-books on Dermatology by American writers have been appearing with bewildering frequency of late. One reason for this increase may be found in the perfecting of modern photography and processes of reproduction, as it is easily possible nowadays to produce a book filled with graphic and accurate representations of cutaneous conditions such as were unknown to the earlier writers. Dr. Hazen says in his preface that his apology for adding another book to the existing collection is, that in his opinion, there is at present no book altogether suitable for either the student or general practitioner, as he regards the large works as too voluminous, while the small books he characterizes as "rather exaggerated quiz compendiums," not sufficiently comprehensive. His attempt has been to describe fully the common diseases, accompanied by illustrations of their histopathology in many

instances. A short introduction by Dr. Gilchrist emphasizes Dr. Hazen's claims to fitness for his task. The book is clearly written, and a judicious amount of space, in relation to the size of the volume, seems to have been given to each topic. The illustrations are very good and very instructive.

*Surgical Operations with Local Anesthesia.* Second Edition. By ARTHUR E. HERTZLER, A.M., M.D., Ph.D., F.A.C.S., Surgeon to the Halstead Hospital, Kan.; the Swedish Hospital, Kansas City, Mo.; and to the General Hospital, Kansas City, Mo. New York: Surgery Publishing Company. 1916.

Four years ago, Hertzler published his first edition. The present volume is one-third larger than the first, and more profusely illustrated, containing about three hundred pages and an equal number of good pictures. The simpler operations were considered in the first volume, but the present work includes most of the major operations. It is true that the technique of producing safe and satisfactory anesthesia is described with far greater detail than is bestowed upon the operative procedures as such, but this is perhaps fair, when the scope and title of the book are considered. The author repeatedly and rightly emphasizes the fundamental importance of a careful and thoroughly developed technique; with the drugs now at our disposal, it is the surgeon's fault if the anesthesia is not complete. But an adequate technique in this as well as in other procedures can be acquired only by study and patient practice. The book is again recommended to students and surgeons.

*Twelve Lectures on the Modern Treatment of Gonorrhea in the Male.* By P. ASCH, M.D., (STRASSBURG). Translated and Annotated by FAXTON E. GARDNER, M.D., Lecturer and Assistant Visiting Genito-Urinary Surgeon, New York Polyclinic; Assistant Genito-Urinary Surgeon, Bellevue Hospital, Out-Patient Department, New York City. New York: Rebman Company. 1915.

This book is not in the least like most small compendiums of knowledge, which it resembles in size and appearance. It consists of twelve short concise lectures on the "Treatment of Gonorrhea in the Male," and it embodies the author's personal briefs and experience, well translated into English. The paper and type are good and the few illustrative sketches are adequate for their purpose.

# THE BOSTON Medical and Surgical Journal

Established in 1812

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, JULY 20, 1916

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.50 per year for all foreign countries belonging to the Postal Union.

An editor will be in the editorial office daily, except Sunday, from twelve to one-thirty p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of proofs. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, Manager,

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

## THE NEW YORK POLIOMYELITIS EPIDEMIC.

THE epidemic of poliomyelitis, whose progress we have noted in previous issues of the JOURNAL, has assumed serious proportions, and at the present writing shows little or no evidence of abatement. The report from New York, on July 13, states that there had been 1557 cases and 311 deaths since the outbreak of the epidemic. These figures show a continuance of the relatively high death rate (over 20%) which has characterized the disease in this outbreak.

Not the least serious aspect of this epidemic is the likelihood, indeed almost the inevitability, not only of its persistence, even in controlled form, throughout the summer in New York, but of its diffusion to other parts of the country. The disease originally appeared in poorer and more crowded quarters of the city, but has extended to other localities; and many of the more well-

to-do residents of the city have taken their children away as refugees. Such migration is almost certain to spread the infection, in addition to other possibilities of its dissemination.

Already many cases have appeared in other communities, though it is by no means certain that these are instances of direct transference of infection. There are at present fourteen cases in Massachusetts, of which three are known to have come from New York. The distribution of these cases is as follows: three in Fall River, two each in Pittsfield, Westfield, New Bedford and Worcester, and one each in Lowell, Lawrence and Haverhill. One death from the disease has occurred at North Adams. No cases of the disease have yet been reported in Boston. In New England, cases have been reported in Vermont, Rhode Island, and Connecticut, but none as yet in Maine or New Hampshire. Eleven cases have occurred in Rhode Island with one death, and two cases in Connecticut. There has been only one case in Vermont.

In other parts of the United States the disease has made sporadic appearance. There are 82 cases in New York State outside of New York City, two cases in Philadelphia, 27 cases in Illinois, with one death in Chicago, one case and one death in Baltimore, two cases in Indiana, three in Minneapolis, one in Nebraska, six cases and one death in Wisconsin, and six cases and one death in Newark, N. J. Five cases were also reported in Montreal on July 7.

In New York, and in all other affected communities, drastic measures for the control of the epidemic have been taken. Of these, almost the most important is the immediate reporting and isolation of suspected cases, and this is a duty which falls primarily upon general practitioners. As a guide to them in dealing with the disease, the Boston Health Department has issued to physicians in this city the following circular letter of instruction, which should be studied and observed by physicians throughout the State:

"The present outbreak of anterior poliomyelitis or infantile paralysis in New York City has brought this disease prominently before the public. Fortunately Boston has no cases of this disease at the present time, and thus far this year but one case has been reported.

"Infantile paralysis is an acute infectious disease, and is to be feared, not only on account of

the great danger to life, but because in many cases where a patient survives it leaves him disabled for life. Permanent paralysis or greatly impaired functions of the arms and legs are the most common results.

"This disease attacks people of all ages, but the greatest incidence is always among children, especially those in the first half decade of life. Children under five years of age furnish usually from 50 to 90% of the cases of poliomyelitis. In some epidemics the disease is almost as prevalent in children between the ages of five and fifteen years as in those under five, but adults, constituting usually about half of the population, seldom furnish more than 10% of the cases, and usually this percentage is smaller. In children under five, the greatest number of cases and deaths occur in those between one and two years of age.

"Strong and healthy children are attacked with as much frequency as weak children, and it does not confine itself to either the rich or the poor.

"Anterior poliomyelitis has been epidemic on both eastern and western hemispheres, in torrid as well as frigid zones, in thinly-settled, remote country districts as well as the thickly-congested sections of our large cities; and, contrary to usual epidemics, it does not necessarily follow the direct routes of travel. During the last epidemic in New York it spread to northern New England, but it did not attack the people in the large cities to the west and south of New York, reached by countless thousands daily, or by the most direct routes of travel. It has been found that the spread of this disease is rapid, but is irregular in its course, and in country districts, where the population is sparse and oftentimes separated by distances, it attacks a greater percentage of the population than in the congested sections of cities. Poliomyelitis usually makes its advent in May and continues until August.

"Boston has been unusually clear of this disease, and whereas in epidemics the mortality reaches about 25%, the percentage has been very low in this city.

"The virus has been found in the tissues and secretions of persons who have died from poliomyelitis and in the secretions of persons acutely ill with the disease, and there are three sources of infection: 1. From those ill with the disease. 2. From those convalescing. 3. From 'passive carriers.'

"The virus in the body exists in the discharges from the nose and throat, and also in the intestinal discharges of those who are ill, and is received into the body through the mucous membrane of the nose and throat. Therefore, kissing, coughing, and sneezing may carry the secretions of nose and throat from the sick to the well. Infected nasal discharges are probably the most common vehicle of spreading the

infection. Persons harboring the disease germs, but showing no symptoms of the disease, may be the cause of its spreading.

"With these facts before us it is the earnest hope of the officials of the Health Department that epidemic infantile paralysis will not strike here. However, preparations have been made, and the department is ready for any emergency. At the present time the Health Department especially desires your coöperation and assistance for the care and control of this disease. By reporting immediately all cases that come to your attention, with the history of the children coming recently to this city from an infected area, and reporting all suspicious cases that may be called to your attention, this threatened outbreak may be averted.

"The office (Fort Hill 5100) is open from 9 a.m. to 11 p.m., Sundays and holidays included, for the report of contacts and cases. Telephone charges may be reversed.

"F. X. MAHONEY, M.D.,

"Health Commissioner."

As a further aid to physicians in reviewing for prompt recognition the symptoms of the disease, the JOURNAL is publishing in another column of this issue a special article by Dr. Francis R. Fraser of New York on the symptomatology and diagnosis of the disease in its acute stages. This article is especially recommended to the medical profession for attentive perusal.

By way of treatment, Dr. Beverly Robinson of New York has suggested the exhibition of ammonium salicylate, which he believes to have a bactericidal value.

The especial attention of physicians is also called to the recently published (July, 1916) number of the *American Journal of Orthopedic Surgery*, which is issued as a symposium on infantile paralysis. In a series of expert papers, this symposium discusses the later surgical treatment of the complications and sequelae of the disease which, during the period succeeding so violent and extensive an epidemic as the present, are certain to be seen in considerably increased numbers.

It is earnestly to be hoped that by the intelligent and alert coöperation of every practitioner of medicine, the suppression of the lamentable epidemic now in progress may be speedily secured and its extension into new fields prevented.

## AMERICAN COMMITTEE FOR MEDICAL PREPAREDNESS.

IN another column of this issue of the JOURNAL we take pleasure in publishing a communication from Dr. Horace B. Arnold on "The Unpreparedness of the Medical Profession." The facts which he points out relative to the status of our profession as regards its readiness for war service are extremely pertinent and significant. That they have not escaped the realization of others, and that steps have already been taken to remove some of the defects of our professional organization for this purpose, is evidenced by the work already accomplished by the advisory committee of civilian American physicians and surgeons on medical preparedness.

This committee was jointly appointed in the spring of 1916 by the presidents of the American Medical Association, the American Surgical Association, the Congress of American Physicians and Surgeons, the Clinical Congress of Surgeons of North America and the American College of Surgeons. Its personnel was as follows:

William J. Mayo, Chairman, Rochester, Minn.; Frank F. Simpson, Secretary, Pittsburgh, Pa.; Frank Billings, Chicago; John F. Binnie, Kansas City, Mo.; Joseph C. Bloodgood, Baltimore; George E. Brewer, New York City; George W. Crile, Cleveland; J. M. T. Finney, Baltimore; Charles L. Gibson, New York City; Robert G. LeConte, Philadelphia; Fred B. Lund, Boston; Edward Martin, Philadelphia; Franklin H. Martin, Chicago; Rudolph Matas, New Orleans; Charles H. Mayo, Rochester, Minn.; Lewis S. McMurtry, Louisville, Ky.; John B. Murphy, Chicago; Robert E. Noble, Washington; Albert J. Ochsner, Chicago; Charles A. Porter, Boston; Charles A. L. Reed, Cincinnati; Emmet Rixford, San Francisco; Hubert A. Royster, Raleigh, N. C.; George E. de Schweinitz, Philadelphia; Henry Sewall, Denver; Richard P. Strong, Cambridge, Mass.; William S. Thayer, Baltimore; Albert Vander Veer, Albany, N. Y.; Victor C. Vaughan, Ann Arbor, Mich.

The committee organized in Chicago on April 14, elected officers and an executive committee, which on April 26 met in Washington and presented to President Wilson the following memorandum.

"We, the undersigned, acting as a committee of the medical profession appointed by the joint

action of the presidents of five national societies, to wit: the American Medical Association, the American Surgical Association, the Congress of American Physicians and Surgeons, the Clinical Congress of Surgeons of North America, and the American College of Surgeons (having an aggregate membership approximating 70,000 medical men), have the honor to present our greetings and to tender to the Federal Government our services toward the medical welfare of the Army and Navy, being prompted to do so by the following considerations:

1. In times of peace as well as in times of war, the medical profession has always held itself in readiness, out of a spirit of patriotism and coöperation, to serve the best interests of the Federal Government.

2. The European war, especially during the first six months, demonstrated a greater need both of medical supplies and of more efficient organization of medical resources, in connection with military and naval activities, than was formerly deemed adequate or necessary.

3. Every soldier and sailor in the service of the Federal Government is entitled at all times to protection in sanitary matters, and to proficient medical and surgical care.

Prompted, therefore, by these considerations, this committee respectfully offers its services in coöperation with the existing medical agencies of the government. Among the services for which at this time the committee specifically tender their coöperation, in conjunction with existing facilities of the Army and Navy for such purposes, are:

1. To establish, through the membership of the above-named medical organizations and their affiliations with local medical societies of the states and territories, an organization that would be in a position to make a comprehensive survey of the medical resources of the country.

2. To make a complete invoice of such resources available in peace and in the emergency of war. This invoice would include not only the names of men available for field or home duty who are trained in the specialties of medicine, surgery, and sanitation, but it would also include in minute detail for each community the equipment of the institutions with which these men are connected, such as hospital facilities, buildings available for hospital use, facilities for transporting wounded men, food supply and drug supply on hand and available, lists of trained nurses and other persons essential for hospital work, etc.

3. To aid in the care of the sick and wounded and the elimination of preventable diseases.

We would respectfully submit that thorough organization of the national civilian and reserve medical resources is of primary importance in the proper preparedness of the country.

For the accomplishment of these ends we desire unreservedly to offer our services."

This offer of service was accepted by the President. The committee completed its organization by adding to its numbers as honorary members the surgeons general of the three national medical services and a half dozen associate members, among whom may be noted Dr. Eugene H. Smith, dean of the Harvard Dental School. Subordinate committees have also been appointed in every state, the Massachusetts committee consisting of the following members:

John B. Blake, Chairman, Boston; Samuel B. Woodward, Worcester; Walter L. Burrage, Boston; Lincoln Davis, Boston; Homer Gago, Worcester; Robert B. Greenough, Boston; Roger I. Lee, Cambridge; Robert W. Lovett, Boston; R. H. Seelye, Springfield.

The immediate duties which the committee purposes specifically to undertake, are the following:

"A. To aid the Medical Department of the United States Army and Navy by making a comprehensive inventory of the especial qualifications of individual civilian physicians throughout the country.

"B. To cooperate with the National Committee of the American Red Cross, in bringing that organization up to the highest standards of medical ideals and to aid in the organization of Red Cross units throughout the country.

"C. The activities of the near future will include a very practical inventory of all civilian medical resources.

"D. Research work and careful investigation along many lines relating to the subject of efficient medical preparedness."

The first report of the committee was issued in Chicago on June 30. Its first step is the selection in various parts of the country of 21,000 physicians who, it is estimated, should be sufficient to care for an army of 3,000,000 men, on the European basis of 7 physicians for each 1000 enlisted men. The plan calls for the selection of physicians by each state on the ratio of 200 physicians to each million of population. To further this end, the committee will endeavor to interest the profession in the desirability of applying for commissions in the medical reserve.

"By a mutual understanding between the National Committee of American Physicians for Medical Preparedness and the National Committee of the American Red Cross, and by an interlocking arrangement of National, State and Local Committees, the former organization has determined to cooperate with the Red Cross in raising its civilian and military work to the highest point of efficiency and in organizing a

considerable number of Red Cross Hospital units, in strict accord with the most recent advances and the highest ideals of medicine. By a Presidential proclamation dated August 22, 1911, the Red Cross was made, substantially, an agency for the organization of a reserve for the medical services of the army and navy, and the units organized by it pass, in time of war, into the medical service of the military forces."

## NATIONAL BOARD OF MEDICAL EXAMINERS.

THE obvious desirability of a standard medical examining body for the entire United States and its territories, led, in 1915, to the foundation by the late Dr. W. L. Rodman, then president of the American Medical Association, of the National Board of Medical Examiners, a voluntary organization whose members were selected from the medical corps of the United States Army, Navy and Public Health Service, from the Federation of State Examining Boards, from other medical organizations and from representative physicians throughout the country.

The Board, as originally constituted, consisted of the following fifteen members:

Surgeon-General W. C. Braisted, U. S. N., President.

Dr. W. L. Rodman, Secretary.

Colonel Louis A. LaGarde, U. S. A., Ret., Treasurer.

Surgeon-General W. C. Gorgas, U. S. A.

Surgeon-General Rupert Blue, U. S. P. H. S.

Medical Director E. R. Stitt, U. S. N.

Assistant Surgeon-General W. C. Rucker, U. S. P. H. S.

Dr. Herbert Harlan, Federation of State Medical Examining Boards.

Dr. Isadore Dyer, New Orleans, La.

Dr. Victor C. Vaughan, Ann Arbor, Mich.

Dr. Henry Sewall, Denver, Col.

Dr. Louis B. Wilson, Rochester, Minn.

Dr. E. Wyllys Andrews, Chicago, Ill.

Dr. Horace D. Arnold, Boston, Mass.

Dr. Austin Flint, New York, N. Y.

Upon the death of Dr. W. L. Rodman on March 8, 1916, Dr. W. L. Biering of Des Moines, Ia., was, on June 13, elected to the Board and Dr. J. S. Rodman has since succeeded to the office of secretary. It is intended that the permanent organization of the Board

shall consist of the three surgeons general, of one representative from each of the government services, of three representatives from the state examining boards and of six members chosen at large from the profession by the National Board of Medical Examiners. The headquarters of the Board is to be at Washington, D. C.

The purpose of the National Board of Medical Examiners of the United States is to establish a standard of examination and certification of graduates in medicine through which, by the coöperation of individual boards of medical examiners, the recipients of certificates of the National Board of Medical Examiners may be recognized for licensure to practice medicine. The policy of the Board is to conduct its examinations on a broad scientific basis of such a high, yet practicable, standard that the holders of its certificates will receive universal recognition. The independence of the Board is furthered by the financial and moral support of the Carnegie Foundation.

The first examination to be held by this Board will begin at the Army Medical Museum, Washington, D. C., on October 16, 1916, and will cover a period of one week. No charge will be made for the examination, but a registration fee of \$5.00 is required. Further particulars may be obtained from the secretary, Dr. J. S. Rodman, 2106 Walnut Street, Philadelphia.

The requirements for admission to this examination are the satisfactory completion of a four-year high school course; two years of acceptable college work, including physics, chemistry, biology and one modern language; graduation from a medical school of Class A in the American Medical Association classification; and a year spent as interne in an acceptable hospital or laboratory. The examinations will be conducted primarily by members of the Board and will be written, oral and practical. Examinations will also be held at the Army and Navy Medical School and at the Hygienic Laboratory of the Public Health Service. The examination will cover the following subjects which will be numerically rated as follows:

1. Anatomy .....	100
2. Physiology .....	75
3. Chemistry and Physics .....	75
4. Pathology and Bacteriology.....	100
5. Materia Medica, Pharmacology, and Therapeutics .....	75
6. Medicine .....	200
7. Surgery .....	200

8. Obstetrics and Gynecology ....	100
9. Hygiene and Sanitation.....	50
10. Medical jurisprudence.....	25

Total .....1000

An average of 75% is required as a passing grade and any candidate who receives a mark below 50% in one subject, or below 65% in two subjects, fails. Candidates failing at the first examination may register for the second examination at the end of the year, but a third examination will not be allowed. Candidates who have been successful and are approved by the Board will be granted certificates, which are not licenses to practice medicine and will not exempt the holders from complying with the legal requirements of the states in which they desire to practice. These certificates, however, will be evidence of high attainment in medical knowledge and it is believed that they will soon be accepted by state boards of registration as evidence for licensure without further examination.

The formation of the National Board of Medical Examiners and the plans for its work represent an attempt to accomplish unofficially the standardization of medical registration throughout the United States which has so long been needed and desired by enlightened practitioners. The movement has already received the endorsement of the American Medical Association and numerous other medical organizations. It is sincerely to be hoped and expected that the successful work of this board may soon win permanent recognition and result in the elimination of the duplicated effort and anomalous diversity of standards resulting from present methods of state examination.

## MEDICAL NOTES.

THE HISTORY OF A TYPHOID CARRIER.—The daily press thus chronicles the history of a typhoid carrier in New York State: "The carrier, Mr. C—, is fifty-five, has a dairy farm in X—, and his milk is sold by others in his city. About sixteen years ago he had typhoid fever, has been in good health ever since and does the work on his farm, including milking, assisted by his son and family.

"At various times suspicion pointed to this milk supply, but nothing definite could be proved against it. In 1913 a new health officer was appointed. He followed up each typhoid

outbreak and found always four to six dairy farms, C's among them, and tests were made among these every time. In 1914 an outbreak was traced to ice cream—milk from C—, but it was thought that the water in which the cans were washed was contaminated. In 1915 an outbreak was defined as possibly due to a few farms, C's among them, and tests were made of all the dealers. Delay in examining the specimens caused the tests to be worthless. C— was warned not to sell milk in N—. Later in 1915 another outbreak occurred, traced to milk of a dealer, P—. There was no trouble on his farm, but it was found that his own supply being short, he was quietly getting about eighty quarts a day from C—. C— was again tested and found to be a carrier. Meanwhile the water supply had been treated and many other possible causes discussed.

"It is an interesting story, showing how insidious the typhoid bacillus is and how the health officer must be a detective as well as a sanitarian."

**AMERICAN ACADEMY OF MEDICINE.**—At the annual meeting of the American Academy of Medicine in Detroit, Mich., on June 12, the following officers were elected for the ensuing year: President, Dr. Jacob E. Tuckerman, (Cleveland); vice-presidents, Dr. Frederick L. Van Sickle, Olyphant, Pa., and Dr. Ray Connor, Detroit, and secretary, Dr. Thomas W. Grayson, Pittsburg.

#### PREVENTION OF FOURTH OF JULY FATALITIES.

It is now over ten years since the beginning of the movement for the so-called safe and sane observation of the Fourth of July, a movement whose progress has been largely aided by the influence of the *Journal of the American Medical Association*, especially in the matter of the prevention of tetanus. The following statistics are the best evidence of the success of this movement. In the year 1899 there were twenty-one deaths in New York City from tetanus following pistol and firecracker injuries. In 1903 there were in the entire United States 415 cases of such injuries. In 1905 the total number of cases was reduced to 104, but of these 87 died. In 1906 there were 89 cases and 75 deaths, of which 10 were in New York City. In 1909 the number of cases rose again to 150 with 126 deaths, of which 7 were in New York City. Since that time the number of cases and deaths has rapidly declined. In 1914 there were only 3 cases, all of which, however, proved fatal, and in 1915 there were 3 cases and 1 death. This rapid decline represents the diffusion, not only among the public but among the profession, of knowledge about the danger of blank cartridge and firecracker wounds, the best method of their treatment, and the possibility of preventing the development of tetanus from such injuries.

**MEDICINE IN CHINA.**—As significant of the present status of medical education in China, the daily press reports as follows a recent conference of the National Medical Association of China, the president of which is F. C. Yen, M.D., of Changsha:

"There were 55 delegates in attendance at this meeting in Shanghai, representing sections separated by about 1200 miles along the country adjacent to the coast from Canton and Hong Kong north to Mukden and Kirin. The Chinese army and navy were also represented.

"In view of the general Western ignorance of the China of today, it is interesting to note that the plaint of Dr. Wu Lien-Teh was the absence of compulsory notification of infectious fevers, and he urged the more thorough adoption of new and progressive ideas. Some of the titles of papers suggest that the Chinese are considering the questions of the day in much the same way as do the Caucasians and with intelligence and knowledge. The 'Medical Education of Nurses' was discussed by Dr. Lujien Tsao of Nanking, a woman graduate of Philadelphia medical schools; while Dr. S. P. Chen urged the reorganization of the medical schools of the country. He proposed the establishment of a central board of control, the reorganization of existing schools, provision for post-graduate study and the equipment of hospitals throughout the country. 'Health as a Factor in National Strength' was the timely title of a paper presented by Dr. Peter, secretary of a Chinese public health council."

**AN IMPORTANT LEGAL DECISION.**—Before Judge William I. Grubb in a United States court recently, a jury determined that novocaine as a synthetic product does not come within the prohibitory provisions of the Harrison Anti-Narcotic Law, inasmuch as it is not a derivative or compound of opium or coca leaves. This decision was rendered in a suit of protest brought by a drug company to recover the tax which had been paid under a ruling of the treasury department.

#### EUROPEAN WAR NOTES.

**APPEAL OF AMERICAN RELIEF COMMITTEE.**—The American Relief Committee, auxiliary to the American Relief Committee in Berlin for Widows and Orphans of the War, has recently issued the following appeal for funds for the continuation of its work. The honorary chairman of this committee is His Excellency, Charles S. Whitman, Governor of New York, and the honorary vice-chairman, His Honor, John Purroy Mitchell, the Mayor of New York City. The chairman is the Honorable George B. McClellan, former mayor of New York, and the treasurer, to whom all contributions should be sent, is John B. Crippins, Esq., 30 East 42d street, New York. Among the leading members of the committee are Nicholas Murray Butler

of New York, President of Columbia University, Henry S. Pritchett of New York, President of the Carnegie Foundation, Mr. Henry W. Taft of New York and the Honorable Charlemagne Tower of Philadelphia. The appeal of this committee is as follows:

"Ever since the outbreak of the war when it became evident that the great struggle was to impose immeasurable suffering upon all nations, Americans living in Berlin have been trying to do what they could to alleviate the situation. An American Relief Kitchen, organized by the American Chamber of Commerce, with Mrs. James W. Gerard as president, was opened, and distribution of food was daily made to hundreds of those in immediate want. At the same time coal and clothing were given as freely as circumstances permitted. The Kitchen was entirely non-partisan and made no distinctions as to nationality.

"This and other endeavors to minister to the all-prevailing misery have been highly appreciated in Germany, and there have been warm expressions of gratitude from many sources. But with the unlooked for proportions to which the war has grown, all ordinary relief methods have broken down, while the demand for help has become more urgent than ever. The number of persons requiring assistance, the constantly multiplying appeals of widows and orphans have brought about a condition calling for redoubled efforts.

"Americans in Berlin have given freely and without stint; but their resources, already straitened by the interruption of commerce incident to the war, have been nearly exhausted. The Relief Kitchen, after nine months of noble work, has been forced to close its doors on account of lack of funds, and that at the very time when its activities were most essential. Indeed, all humane exertions which resident Americans have felt called upon to undertake are in danger of extinction.

"Rather than let this all-important work go by default and thus allow America, so active elsewhere, to appear to neglect the call of humanity in this one field, the American Relief Committee in Berlin for Widows and Orphans of the War, under the patronage of Hon. James W. Gerard, the American Ambassador, and Her Highness, the Princess of Hohenlohe, has been formed and has appealed to their fellow-citizens at home to assist them.

"The American Auxiliary Committee has come forward in response to this appeal, and hopes to raise a substantial sum, which will be forwarded without deductions of any kind to the American Relief Committee in Berlin, and expended by the Red Cross of Berlin in their relief work among widows and orphans of the war.

"Necessary clerical expenditures already have been provided for by the members of the Committee.

"The Committee cannot handle food and clothing; but money not only will relieve in some measure the very real suffering of non-combatants, but will also prove to the German people, so long friendly to America, that America, on her part, is willing to give of her plenty, wherever humanity demands."

**WAR RELIEF FUNDS.**—On July 14 the totals of the principal New England relief funds for the European War reached the following amounts:

Belgian Fund .....	\$132,945.12
Allied Fund .....	123,912.00
French Wounded Fund .....	99,146.80
Army Huts Fund .....	66,739.60
French Orphanage Fund .....	57,397.05
Armenian Fund .....	54,892.77
Polish Fund .....	39,052.37
Facial Hospital Fund .....	23,135.51
Italian Fund .....	20,592.34
Permanent Blind Fund .....	1,003.70

#### MEXICAN NOTES.

**BASE HOSPITALS AT THE FRONT.**—Report from San Antonio, Texas, on June 30, states that two large base hospitals capable of caring for 500 patients each have been established in that city and at Fort Bliss. A smaller base hospital has also been established at Douglas, Ariz., and there are to be others at Fort Crockett, Galveston, Eagle Pass, Laredo and Nogales. Numerous camp hospitals have been established along the frontier.

**FIELD HOSPITALS AND AMBULANCE COMPANIES.**—There are at present in the United States Army seven field hospitals and seven ambulance companies. Steps have already been taken by the Government to equip each field hospital with a motor truck and all field ambulance companies with motor ambulances.

**BROWNSVILLE MILITARY HOSPITAL.**—Report from Brownsville, Texas, on June 27, states that funds are being raised for the enlargement and maintenance of the Brownsville Military Hospital. The National Red Cross has given \$1000 and Major Henry L. Higginson of Boston \$10,000 for this purpose. When completed the hospital is to contain 300 beds.

**SECOND MASSACHUSETTS FIELD HOSPITAL COMPANY.**—The first Massachusetts Field Hospital Company is already at the front with the mobilized Massachusetts Militia. A second field hospital and ambulance company has been organized by Dr. Charles R. Morgan of Boston, who will be its captain, with Dr. W. H. Young and Dr. H. F. Parker as lieutenants. This company has an enrollment of 67 men, six officers and nine members of the quartermaster's department. Its members have already taken the Federal oath, been inspected and gone to Framingham for encampment prior to departure for Mexico. Dr. Morgan served with

the medical department of the United States Navy during the Boxer uprising in China in 1900 and in the Philippines in 1901 and 1902. He served for a time as assistant surgeon in the navy and for three years has been first lieutenant in the medical corps of the Massachusetts National Guards.

**SANITARY ORGANIZATION OF THE ARMY.**—Report from Washington, D.C., on July 3, states that Lieutenant Colonel Edward L. Munson and Majors R. B. Miller and William N. Bispham of the United States Army Medical Corps have left that city for San Antonio, Texas, to assume charge of the sanitary organization in connection with the National Guard camp at the front. It is also announced that the United States War Department will furnish sanitary equipment to all National Guard organizations, including material for ambulance companies and field hospitals. The Department will purchase four hundred motor ambulances and large quantities of bedding and other hospital supplies. New medical supply depots have been established at El Paso and San Antonio. Existing hospitals have been enlarged and additional accommodations will be built. Orders have been placed for 200,000 mosquito bars, and it is intended that every militia soldier who has not already been vaccinated against smallpox and typhoid shall be compelled to receive this protection.

**MASSACHUSETTS DENTAL CORPS.**—Adjutant General Cole of Massachusetts has called attention to the desirability of organizing and sending to El Paso, for service with the Massachusetts militia, a dental corps to consist of six qualified dentists. It is expected that the Governor will issue the necessary authorization for the establishment of such a corps.

**MASSACHUSETTS MEXICAN RELIEF FUND.**—Two funds have already been initiated in Massachusetts to relieve the stress incident to the Mexican situation. The first is that of the Massachusetts Volunteer Aid Association, whose purpose is to relieve distress among the families of Massachusetts soldiers, and to furnish supplies of relief to the soldiers themselves. On July 14 the total of this fund amounted to \$66,897.50. The other fund is that of the Special Aid Society for American Preparedness, which on the same date reached a total of \$9,423.40.

On July 10 the Massachusetts Volunteer Aid Association issued the following second appeal for contributions to its fund:

"On June 26, Governor McCall summoned to the council chamber certain citizens, men and women of our State, and requested them to organize the Massachusetts Volunteer Aid Association for the purpose of helping the women and children of the men called to military service by the President of the United States, who receive no adequate assistance from their em-

ployers, and to assist these men in every needed way.

"The committee of citizens summoned has organized as directed and has taken up the work with diligence and zeal. Everyone has been invited to become a member of the Association by subscribing \$1 or more and the committee is now engaged in giving help, acting only after the most careful inquiry.

"Subscriptions, large and small, have been invited, and some money has been raised, but not nearly enough to carry on the work which has proven to be necessary. As many families are actually without food and money, subscriptions are needed immediately.

"So long as our men are in service, war or no war, many of their families need help, and the committee asks our citizens to send their subscriptions at once to George C. Lee, treasurer, 50 State street, Boston.

"HENRY L. HIGGINSON,

"DANIEL G. WING,

"WILLIAM A. GASTON,

"PHILIP STOCKTON,

"AUGUSTUS P. LORING,

"WILMOT R. EVANS,

"HENRY PARKMAN,

"W. CAMERON FORBES,

"JAMES M. PRENDERGAST,

"W. MURRAY CRANE,

"FRANK G. WEBSTER,

"A. C. RATSHESKY,

"Finance Committee."

**BASE HOSPITAL AT THE MAYO CLINIC.**—On July 10, it was announced that Colonel Jefferson R. Kean of the United States Army Medical Corps, Director General of military relief of the American Red Cross, had received at the American Red Cross Headquarters in Washington, a letter from Dr. William J. Mayo of Rochester, Minn., offering to organize a base hospital whose personnel and equipment should be furnished by the Mayo Clinic. The number of medical officers in this hospital would be 23, the number of beds would be 500, and the estimated cost of equipment, \$25,000.

**MASSACHUSETTS BASE HOSPITALS.**—The Massachusetts branch of the American Red Cross has announced its intention of raising funds to provide full war equipment for the three base hospital units to be established at the Boston City, Massachusetts General and Peter Bent Brigham hospitals in this city. A committee has been appointed and has issued an appeal for the sum of \$200,000 for this purpose. In addition, a fourth base hospital is to be established in western Massachusetts, for which further subscriptions of \$50,000 are requested by another committee from that part of the State. On July 14 a total of \$67,922.00 had already been raised towards the former sum. Each of the four base hospitals thus provided is to be equipped with

five hundred beds and four motor ambulances, and each will have a total complement of 196 physicians, surgeons and attendants. In addition, the committee purposes to establish an ambulance corps as an adjunct to each hospital, at a cost of \$30,000, and, in the event of war, a hospital train costing \$15,000 to bring troops from the front. A hospital ship is another possibility under consideration.

**MASSACHUSETTS FIELD HOSPITAL FUND.**—The following extract from a recent letter to a Boston physician by a lieutenant of the Massachusetts Field Hospital Company, No. 1, now on service in Camp at Fort Bliss, El Paso, Texas, is self-explanatory:—

"Do you think you could get the Massachusetts Medical Society interested enough in us to give us a little aid? We are suffering for want of transportation facilities. We have no horses, but expect to become motorized at some time,—when, I don't know. We have been promised by some Back Bay ladies a portable kitchen and a motor ambulance. What we most need now is a couple of motor-cycles with sidecars, to get about quickly and run errands with. As we are so far from town, hours are wasted in getting about on a car service crippled by a strike now going on. I ask you, thinking perhaps you could start something to help us."

In accordance with this appeal, and after conference with officers of the Massachusetts Medical Society, it is proposed to establish a fund to purchase the needed equipment. Contributions to this fund, from physicians and others, are earnestly solicited, and should be sent to Dr. Samuel B. Woodward, 58 Pearl Street, Worcester, or to Dr. Paul Thorndike, 14 Marlborough Street, Boston.

#### BOSTON AND NEW ENGLAND.

**THE WEEK'S DEATH RATE IN BOSTON.**—During the week ending July 15, 1916, there were 199 deaths reported, with a rate of 13.65 per 1000 population, as compared with 197 and a rate of 13.69 for the corresponding week of last year. There were 31 deaths under 1 year, as compared with 35 last year; and 53 deaths over 60 years of age, against 53 last year.

During the week the number of cases of principal reportable diseases were: diphtheria, 35; scarlet fever, 10; measles, 165; whooping cough, 20; typhoid fever, 4; tuberculosis, 45.

Included in the above were the following cases of non-residents: diphtheria, 10; scarlet fever, 3; typhoid fever, 1; measles, 2; tuberculosis, 3.

Total deaths from these diseases were: diphtheria 1; measles, 5; tuberculosis, 21; whooping cough, 1.

Included in the above were the following deaths of non-residents: diphtheria, 1; tuberculosis, 2.

**DENTAL CLINIC AT BOSTON DISPENSARY.**—On Monday of last week, July 10, a new dental clinic was opened at the Boston Dispensary in

charge of Dr. Kurt H. Thoma of the Harvard Dental School. Nominal fees are charged to cover the cost of material and of administration. The clinic is to be held on Monday and Friday at 7 p. m.

**BOSTON BABY HYGIENE ASSOCIATION.**—On July 6, the Boston Baby Hygiene Association issued a statement of its work during the preceding month and half-year. During the first six months of the year 3370 babies were under supervision by the Association, and over 2000 of these were under care in the month of June, an increase of 113 over June, 1915. Contributions to the sum of \$300 have been received towards the opening of a new station at Grove Hall. Seventeen nurses are now employed by the Association, and an extra nurse is maintained at the South Station by the Federation of Women's Clubs. Dr. J. Herbert Young, director of the Association, announces the appointment of the following conferent physicians:

Dr. Edwin A. Meserve, Dr. N. M. Scott, Dr. Jeremiah A. Green and Dr. A. B. Lyon.

**HOSPITAL BEQUEST.**—The will of the late Marion C. Goodwin, filed recently at the Probate Office, contained a bequest of \$500 to the Children's Hospital, Boston.

### Miscellany.

#### RÉSUMÉ OF COMMUNICABLE DISEASES FOR MAY, 1916.

THE outstanding features of the communicable disease situation for May are the unusually high mortality from measles, the low incidence of typhoid fever, and the sharp outbreak of septic sore throat in Watertown.

**Prevalence.** The total number of cases of communicable diseases reported for May is about the same as for the corresponding month last year. It is considerably above the five-year average for the month of May. The case incidence per hundred thousand population for May, 1916, was 218, while the average for the five-year period (1910-1914) was 190. This increase above the average is due to the unusual prevalence of measles and the better reporting of whooping cough. Measles continue to be the most important single factor in our communicable disease reports. It is prevalent in every part of the state.

**Distribution.** The distribution of the various communicable diseases is of interest.

**Measles.** Springfield and Brockton remain the centers of greatest intensity in this infection. However, during May the following cities and towns have exceeded their endemic index. Endemic index signifies the average for five years of reported cases exclusive of

epidemics. This index is applied to each city and town for each month for every communicable disease.)

The numbers in the first column indicate the endemic index for that city or town. The numbers in the second column indicate the cases reported during the current month.

	Endemic Index.	Current Year.
Abington .....	2	43
Adams .....	0	31
Amesbury .....	1	12
Attleboro .....	1	79
Avon .....	0	37
Bridgewater .....	4	44
Brockton .....	39	451
Carver .....	0	14
Chatham .....	0	12
Chelmsford .....	0	22
Chilcopee .....	7	58
Clinton .....	2	43
Duxbury .....	0	16
E. Bridgewater .....	1	34
Erving .....	0	32
Essex .....	1	9
Fall River .....	11	42
Fitchburg .....	16	55
Frammingham .....	24	37
Hanson .....	0	15
Hanover .....	0	22
Hardwick .....	0	23
Holbrook .....	1	16
Lowell .....	105	182
Ludlow .....	0	28
Lynn .....	21	42
Mansfield .....	2	14
Marshfield .....	0	44
Mendon .....	0	42
Methuen .....	2	16
Montague .....	1	12
Needham .....	0	11
Newton .....	81	168
Palmer .....	1	12
Rockland .....	0	42
Rockport .....	0	9
Shirley .....	0	13
Springfield .....	46	405
Tyngsboro .....	0	21
Ware .....	0	14
Wareham .....	0	28
Warren .....	0	35
Westfield .....	3	21
Whitman .....	2	35
Worcester .....	90	331

*Scarlet Fever* shows a decrease in amount both in comparison with May, 1915, and with the average for the five-year period. The most important focus of infection seems to be at Quincy. From the investigations of the State District Health Officer, the disease appears to be being spread by mild and ambulant cases. The following cities and towns have exceeded their scarlet fever endemic index for the month of May:

	Endemic Index.	Current Year.
Amesbury .....	1	8
Bridgewater .....	1	7
Cambridge .....	11	21
Clinton .....	1	8
Dalton .....	0	9
E. Longmeadow .....	1	8
Holyoke .....	14	40
Lexington .....	0	6

	Endemic Index.	Current Year.
Milton .....	1	12
Newburyport .....	1	6
North Adams .....	0	7
Northampton .....	4	12
Peabody .....	1	11
Quincy .....	8	42

*Whooping Cough* has shown a slight increase in the number of reported cases as compared with May, 1915. The considerable increase noted, as compared with the five-year period, is doubtless due to the better reporting of this disease. The following cities and towns have exceeded their whooping cough endemic index for May:

	Endemic Index.	Current Year.
Amesbury .....	0	7
Braintree .....	5	26
Brockton .....	7	66
Cambridge .....	9	45
Canton .....	1	9
Chelsea .....	2	14
Danvers .....	0	14
Dudley .....	0	24
Fall River .....	3	26
Fitchburg .....	2	21
Haverhill .....	4	23
Lawrence .....	12	21
Lexington .....	0	10
Medford .....	3	13
Wellesley .....	0	35

*Diphtheria* shows a gratifying decrease in amount. The case incidence per hundred thousand is considerably lower as compared with May, 1915, and also as compared with the five-year period. There are at the present time no important foci of diphtheritic infection in the state. However, the following cities and towns have exceeded their endemic index for diphtheria for the month of May:

	Endemic Index.	Current Year.
Amesbury .....	1	7
Brockton .....	9	26
Everett .....	4	10
Fitchburg .....	4	15
Lawrence .....	9	27
Oxford .....	0	7
West Springfield .....	0	5

*Tuberculosis.* The looked-for increase in the number of reported cases of this disease through the newly-established dispensaries is disappointing. During May there was a decrease in the number of reported cases, both in comparison with the same month last year and with the five-year period. It had been hoped that with the dispensaries in good working order that we would be getting fuller reports of cases. The subject is now being taken up through the State District Health Officers.

*Typhoid Fever.* A remarkably low incidence of typhoid fever is to be noted. Reports for the month show a decreased incidence, both in comparison with May, 1915, and with the five-year period. It is also to be noted that the fatality rate for this disease more nearly approached normal during last month.

**Mortality.** As usual, the most important single factor in the month's mortality is tuberculosis. The most striking factor, however, is the fact that there were 40 deaths from measles during the month. These deaths were distributed as follows: Boston 12, Brockton 7, Worcester 7, Springfield 4, Chicopee 2, Fall River 2, and 1 each from Attleboro, Cambridge, Lawrence, Lynn, New Bedford and Woburn. This is a striking commentary on the generally accepted belief that measles is not a "dangerous disease." Diphtheria, with 39 deaths, is a striking feature, even though it is below the average. We do not appear to be making satisfactory progress in controlling the mortality from this disease. Scarlet fever and whooping cough combined to cause 32 deaths, while typhoid fever was given but eight times as a cause of death.

**Epidemics.** During the course of the month there was a sharp outbreak of what proved to be septic sore throat in Watertown. Physicians of that town were sending to the local board of health laboratory cultures for a severe type of sore throat. The early diagnosis was that of a staphylococcal infection; later developments have proved that it was a hemolytic streptococcus. Investigations showed that all of the families were taking milk from the same milkman. An inspection of the dairies on this producer's route revealed a single cow with an antrophied quarter from which was obtained a small amount of pus. A special bacteriological examination is under way upon orders from the local board of health. The cow was slaughtered; the entire milk supply has been pasteurized.

Three additional cases of anthrax were reported from Woburn during the month. All the cases reported to date have been handlers of Chinese hides.

The diphtheria situation at the Shirley Industrial School for Boys is improved. There have been no clinical cases for some time, and the few remaining boys with positive cultures are isolated in a camp remote from the rest of the school.

**Rare Diseases.** Trachoma was reported from Boston (4), Brookline (1) and Lowell (1). Cerebro-spinal meningitis was reported from Boston (3), Methuen (2), Walpole (2), Arlington (1), Ipswich (1), Northampton (1), Somerville (1) and Springfield (1). Malaria was reported from Boston (3), Marblehead (1) and Worcester (1). Pellagra was reported from Worcester (2), Boston (1), Northampton (1), Taunton (1) and Winchester (1). Septic sore throat was reported from Boston (7), Fall River (4), Somerville (3), Chelsea (1), Chicopee (1), and Westfield (1). Dog-bite was reported from Boston (12), Brockton (7), Worcester (7), Springfield (4), Chicopee (2), Fall River (2), and one case each from Attleboro, Cambridge, Lawrence, Lynn, New Bedford and Woburn.

## Correspondence.

### THE "UNPREPAREDNESS" OF THE MEDICAL PROFESSION.

Boston, July 7, 1916.

Mr. Editor:

In the JOURNAL of July 6, in an editorial on "Medical Aspects of the Mexican Situation," you make the following statement:—

"The occasion and opportunity have arrived when the medical corps of the army and navy, the medical officers of the national guard, and in the event of extensive hostilities, civilian members of the profession will either demonstrate or fail to demonstrate their fitness to deal competently and creditably with the medical urgencies that arise in time of war; and it is most earnestly to be hoped and expected that this demonstration will be in every respect a credit to the American profession." (The italics are mine.)

The natural pride which you take in the medical profession has led to a statement which, in my opinion, is not justified. Let us look a few unpleasant facts in the face.

I believe that, in the event of extensive hostilities, at the present time the medical corps of the army and navy and of the national guard would be found entirely inadequate in numbers, and that the civilian members of the profession would be unable to acquit themselves in such a way that the profession should be proud of them. I know that they would all acquit themselves with great credit in one sense—in their earnest endeavor to accomplish the impossible; but the accomplished results would hardly be creditable.

In the same number of the JOURNAL, page 32, under the head of "Deficiencies of the Medical Service," you call attention to the fact that "On a war footing of 1600 men, each regiment has but four surgeons, who, under conditions of field service in war, are obviously insufficient. In all foreign countries the allowed ratio is seven surgeons to 1000 men." Yet the European War has shown that the allowance of surgeons abroad almost double that in this country—has proved inadequate to meet the demands of modern warfare. The inadequate number of our surgeons is not the fault of the medical corps of the army and navy, but of the Congresses that have refused to make proper provision for the medical care of our soldiers.

If we needed any proof of the inadequate number of medical officers provided for the army, it is to be found in the recent mobilization of the militia. The medical officers have been overtaxed with the duties of mustering in 100,000 men from the militia. What would happen "in the event of extensive hostilities," when we would need in addition a volunteer army of 500,000 or 1,000,000 men?

In such an event they must, of course, turn to the civilian members of the profession, but how many of us know anything about the duties of medical officers? And there would be no available army officers to teach us. This fact has been brought home to me by the present difficulties of the Harvard Graduate School of Medicine in trying to give the course in military medicine which is announced for July.

Recognizing the importance of preparedness on the part of the medical profession, the Graduate School decided last November to inaugurate instruction in military medicine. Major Chamberlain, of the medical corps of the army, was selected by Surgeon General Gorgas to give this instruction, but he could not be sent to Boston until July. All plans were completed for a course of daily lectures to begin July 5, when, at the last moment, it was found that Major Chamberlain could not be spared from the army or the Mexican border. Fortunately, we had already

received his typewritten lectures, and it was thought that some other medical officer of the army could be found to deliver these lectures. Enquiry showed, however, that *not a single officer of the medical corps of the army or of the militia could be spared for this purpose*, so overwhelmed are they by the duties of mobilization and recruiting.

Let us ask ourselves seriously, if we are interested in having the medical profession acquire itself creditably "in the event of extensive hostilities," what would have happened if the United States had found itself suddenly confronted with a war with a first-class power instead of with a possible war with Mexico. Unless the medical profession could creditably meet such an emergency, it is not "prepared" as it ought to be.

It is probable that through typhoid inoculation we should make a better record in one respect than we did in the Spanish-American War, but are we any better prepared in other respects? The medical profession cannot be proud of its record in that war. The records show officially that the incidence of typhoid fever was 88 per thousand, but a board of investigation, consisting of Reed, Vaughan and Shakespeare, came to the conclusion that the rate should have been stated as 192 instead of 88 per thousand. Compare this with the record in the Civil War of 62 per thousand,—and let the profession hang its head in shame for its unpreparedness for military duty in 1898. Are we civilians essentially better prepared in 1916? My answer is "No."

I believe it is the duty of medical schools to include military medicine in the curriculum, that it is the duty of graduate medical schools to organize courses in this subject for members of the profession, and that it is the duty of all physicians in civil life, who might be needed in the emergency of war, to learn at least the rudiments of the duties of a medical officer.

The Harvard Graduate School of Medicine began its course July 5, as announced, and will give a creditable course in military medicine in spite of the handicaps. It will offer similar instruction on a more extensive scale next fall.

Yours very truly,

H. D. ARNOLD.

#### SICKNESS SURVEY OF BOSTON.

Boston, July 8, 1916.

Mr. Editor:

For the week beginning July 17 there is to be made, by the Metropolitan Life Insurance Company, a "sickness survey" of Boston; like the survey made in Rochester a while ago.

There can be no question of the desirability of the exact knowledge of morbidity to be gained in this way, and while Dr. Frankl is running the affair, some co-operation by the profession will help. This need only take the form of answering inquiries as to diagnosis in doubtful cases, in reply to letters of inquiry that will come through Dr. Mahoney of the Health Board.

The profession may rest assured that this survey is intended only to get knowledge of actual conditions,—very essential these days, in view of the probably impending sickness insurance laws, in shaping which medical men must do their share, if they wish for a proper status and proper treatment when such laws become effective.

Very truly yours,

FREDERIC J. CORTON, M.D.

#### RESIGNATIONS.

PROFESSOR SELSKAR M. GUNN has resigned as director of the Division of Hygiene of the Massachusetts State Department of Health.

DR. EMERY R. HAYHURST has resigned as chief of the Division of Occupational Diseases of the State Department of Health of Ohio.

#### NOTICES.

CHANGES IN THE MEDICAL CORPS, U. S. NAVY, for the week ending July 1, 1916.

June 24.

Surgeon H. C. Curl, *Alabama to Rhode Island*.

Surgeon J. S. Taylor, *Rhode Island to Alabama*.

June 26.

P. C. Cook, detached *Louisiana* to home and wait orders.

Surgeon T. W. Richards, to Military Relief Division, American Red Cross, Washington, D. C.

June 28.

Surgeon A. W. Dunbar, detached Naval Academy, Annapolis, Md., to home and wait orders.

June 30.

Assistant Surgeon C. H. Dragoo, to Naval Hospital, Newport, R. I.

NOTE: Medical Director S. F. Cones, retired, died at Cambridge, Mass., May 1, 1916.

CHANGES IN THE MEDICAL CORPS, U. S. NAVY, for the week ending July 8, 1916.

Cable from Commander-in-Chief Asiatic Fleet, June 29, 1916.

P. A. Surgeon M. A. Stuart, detached *Wilmington* to home and wait orders.

Assistant Surgeon Talmadge Wilson, detached Naval Hospital, Yokohama, Japan, to *Wilmington*.

#### BELGIAN PHYSICIANS' RELIEF FUND.

REPORT OF THE TREASURER OF THE COMMITTEE OF AMERICAN PHYSICIANS FOR THE AID OF THE BELGIAN PROFESSION FOR THE MONTH OF JUNE, 1916.

No contributions for the month of June, 1916.

Previously reported receipts,..... \$7941.86

Previously reported disbursements:

1625 standard boxes of food at \$2.20—\$3575.00

1274 standard boxes of food at 2.30.. 2930.20

333 standard boxes of food at 2.28.. 804.84

Total disbursements..... \$7310.04

Balance..... \$ 631.82

F. F. SIMPSON, M.D., *Treasurer*,  
7048 Jenkins Arcade Bldg.,  
Pittsburg, Pa.

#### RECENT DEATHS.

DR. FREDERICK W. K. VON LIBERG, a laryngologist who for some years has had expert care of the German Emperor, died in Berlin on July 9.

### HEMOPTYSIS AS A SYMPTOM.\*

By FREDERICK T. LORD, M.D., BOSTON.

OF the various publications which have dealt with this subject, the monographs by John Ware (On Hemoptysis as a Symptom, from the publications of the Massachusetts Medical Society, Boston, 1860) and by Stricker (Ueber Lungenblutung in der Arnee, Festschr. z. 100 jährigen Stiftungsfeier d. med. chir. Friedrich Wilhelms Inst. Berlin, 1895) are especially noteworthy. Of 329 cases of hemoptysis observed by Ware the bleeding was ascribed to tuberculosis in 190, and 62 (18%) recovered without subsequent symptoms to suggest pulmonary tuberculosis. It appears from Stricker's investigation of 900 young and strong soldiers with hemoptysis in the Prussian Army, that of 480 in whom the hemorrhage occurred without recognizable cause or after a "cold," 417, or 86%, were certainly or probably tuberculous; of 213 in whom the bleeding followed the ordinary exertion of military exercise, 176, or 82%, were ascribed to tuberculosis, and of 118 cases in which this symptom came on after more severe exertion (as in the gymnasium, in riding or in swimming), 76, or 64%, were thought to be tuberculous.

In all large series of clinical cases of hemoptysis in which an inquiry is made concerning

the proportion to be ascribed to tuberculosis, the question of the relation of a certain number to this disease must remain unanswered without an appeal to more definite data than can be accumulated on patients during life. The frequency with which hemoptysis is not followed by outspoken tuberculosis has made the interpretation of the symptom difficult, and has led to a feeling of uncertainty as to the cause, especially in those cases in which it occurs in patients with good family history, in apparent health and without attendant manifestations of tuberculosis. Although it is apparent from the well-known tendency of tuberculosis to undergo spontaneous arrest that apparent recovery, as in Ware's 62 cases, is not an assurance against this disease as the underlying cause, yet the question of the significance of hemoptysis cannot be answered with assurance without further evidence than this. Stricker's cases, in which the hemoptysis appeared to be due to certain or probable tuberculosis in diminishing percentage as the physical exertion increased, suggest the possibility that exertion itself may be a sufficient cause of the bleeding.

In the attempt to reach a more definite conclusion as to the meaning of this symptom, 549 clinical cases of hemoptysis have been reviewed, and there are included in this number those instances which have occurred at the Massachusetts General Hospital, at the Channing Home and in my private records. In addition to this group of clinical cases, 307 instances of hemoptysis with autopsy have been found in the records of the Massachusetts General Hospital. A useful division may be made between those

\* Presented at the Twelfth Annual Meeting of the National Association for the Study and Prevention of Tuberculosis, Washington, May 12, 1916.

cases in which the bleeding comes out of a clear sky, or when cough and scanty expectoration alone cloud it, and those in which the hemoptysis is but one of the symptoms of pulmonary or other disease. It is of interest also to note the probable frequency of the various causes and to inquire as to the influence of hemoptysis on the course of pulmonary tuberculosis. These matters are discussed under the headings which follow:

#### HEMOPTYSIS OUT OF A CLEAR SKY.

Excluding from consideration all cases in which the diagnosis has not been established, there are thirty instances of hemoptysis in this group. In these the hemoptysis was an initial event, unpreceded or followed by pulmonary or other symptoms or accompanied only by cough with or without scanty expectoration. In this number are included twenty clinical cases with sputum positive for tubercle bacilli at the time of the bleeding or later in their course. Other clinical cases, of which there are a considerable number with hemoptysis out of a clear sky, but in which definite proof of the cause is lacking, are left out of consideration as of undetermined origin. The ten remaining were autopsy cases and nine, of which three may be mentioned in greater detail, showed obsolete, inactive or active pulmonary tuberculosis. Thus with one exception all the proved cases in this group were tuberculous.

The three cases already referred to may be summarized as follows. One was the case of a man of 46, who entered the Massachusetts General Hospital in 1898 with a history of having coughed up a lump of blood as big as an egg twenty-four years before after rowing a race. The hemoptysis was not preceded or followed by pulmonary symptoms. He died in Hospital following an operation for cancer of the stomach, and at autopsy (274) obsolete tuberculosis of the lungs and bronchial lymph glands was found as the probable explanation of the bleeding. A second instance is that of a woman of 28, who entered in 1896 with the story of having had a hemorrhage two years before while stepping off a car. She began to cough only four weeks before admission and died from a recurrence of the bleeding. At autopsy (XI-204) the lungs showed tuberculosis with cavity formation. A third example is that of a man of 53, who entered in 1915, and stated that twenty years before, for a time, at intervals of every few months, he coughed up a mouthful of blood. Cough did not precede the hemoptysis, but slight hacking cough followed for a few weeks only. There were no subsequent symptoms referable to the lung, and he died in Hospital from perforation of a gastric ulcer. At autopsy (3530) obsolete tuberculosis of the lungs was found.

The single exception to the tuberculous origin of hemoptysis in this group illustrates an uncommon cause. This was the case of a man of

37, who entered the Hospital in 1904 with a history of winter cough without expectoration for three years. He had an abundant hemoptysis three days before entrance, and death occurred two days after admission from a recurrence of the hemorrhage. At autopsy (1196) syphilitic ulceration of the trachea and bronchi, with rupture of a large branch of the pulmonary artery into the right primary bronchus, was found.

Although other causes in rare instances are found in this group, none have come under my personal observation. Authentic examples of hemoptysis from the ulceration and rupture of anthracotic or tuberculous glands into the air passages, echinococcus disease of the lung, new growth of the bronchi and infection with *Distoma Ringeri* (endemic hemoptysis), may be found in the literature.

To judge from these cases it may be stated as a clinical rule, subject only to rare exception, that hemoptysis out of a clear sky or when cough and scanty expectoration alone cloud it is due to pulmonary tuberculosis. The rule seems to hold as well in those cases in which the hemoptysis occurs during a mild acute respiratory infection, after exertion, moderate injury or without any apparent cause. Exertion of itself cannot be regarded as an adequate cause of hemoptysis, but it may lead to bleeding earlier than would otherwise occur in a patient with tuberculosis owing to the added strain on the walls of blood-vessels already weakened by disease. Initial hemoptysis, even though the only symptom, without subsequent manifestations of pulmonary disease and the maintenance of full health until life is terminated by some other cause, is to be regarded as of probably tuberculous origin. Unless care is exercised in taking the history that all symptoms are included and it is established that the hemoptysis is an uncomplicated event, the situation may be wrongly interpreted. Hemoptysis from pulmonary embolism arising in consequence of latent venous thrombosis, for example, is likely to be accompanied by such other symptoms as dyspnea and pain in the side which serve to suggest that the case belongs in the second group.

#### HEMOPTYSIS OUT OF A CLOUDY SKY.

Cases in which the hemoptysis is an initial and uncomplicated event, justifying their inclusion in the foregoing group, comprise but a small proportion of the series. Preceding or accompanying symptoms or signs of pulmonary or other disease are more commonly present, and in this group, which may be termed hemoptysis out of a cloudy sky, in contradistinction to the preceding, the causes multiply and all enumerated in the list which follows are included.

#### THE CAUSES OF HEMOPTYSIS.

Of the various causes in the probable order of frequency, pulmonary tuberculosis doubtless occupies first place in consideration of the high incidence of this disease and the occurrence of

hemoptysis in about 60 per cent. of all cases at some time in their course. It is represented among the 307 autopsy cases at the Massachusetts General Hospital by only 27 cases, owing to the usual exclusion of patients in the active stage of the disease from the wards of the hospital. Chronic passive congestion probably occupies second place, but heads the list of the autopsy series with 105 cases. Then follow lobar (not broncho-) pneumonia, with 100 cases, pulmonary infarction with 48 cases, non-tuberculous pulmonary suppuration with 14 cases, aortic aneurysm with 7 cases, new growths of the lung with 5 cases and ulceration of the trachea and bronchi due to syphilis in one case.

Copious bleeding is seldom seen apart from pulmonary tuberculosis, occasional instances of abscess and gangrene, ruptured aneurysm, and ulceration of the trachea and bronchi. Insignificant hemorrhage and prominence of other symptoms and signs are the usual complex in chronic passive congestion, lobar pneumonia, pulmonary infarction, abscess, gangrene and new growth. Other causes than those enumerated in the list are rare and not found among the autopsied series. They may be grouped for the sake of completeness under such headings as mechanical injuries, toxic agents, such as the fumes of irritating gases, constitutional diseases (hemophilia, leukemia, hemorrhagic purpura and scurvy, animal parasites (pulmonary distoma, hepatic distoma), echinococcus disease (filaria sanguinis, filaria lymphatica), leprosy, actinomycosis and aspergillosis.

Our records are of interest in a negative sense in their failure to confirm the still too prevalent belief that vicarious menstruation is an adequate cause of hemoptysis, no example of which is found in the autopsy series. This and other evidence indicate that it cannot properly be regarded as a cause apart from some pulmonary lesion which is tuberculous in the great majority of the cases. Hemoptysis in the course of disturbances of the nervous system, in patients with the so-called "arthritic diathesis" (Sir Andrew Clark's type) and in those with high blood pressure, is likely to find its true explanation in one of the above-mentioned groups.

#### INFLUENCE OF HEMOPTYSIS ON THE COURSE OF TUBERCULOSIS.

Finally, I should like to refer to the influence of hemoptysis on the course and termination of the tuberculous cases. For the most part the bleeding is intercurrent and without any appreciable influence upon the course of the underlying disease, but in certain cases the hemoptysis is a direct cause of the fatal termination, the patient dying in consequence of the loss of blood or as a result of suffocation. Hemoptysis was thus an immediate cause of death in five of this series. Of greater frequency and importance, however, is the unfavorable influence which hemoptysis may have on the spread of the tuberculous process in consequence of the aspiration

of infected blood into neighboring or remote parts of the lung. This unfortunate occurrence is very clearly suggested in certain instances under observation when patients with normal temperature have hemoptysis and then in the following twenty-four to thirty-six hours the temperature rises and remains elevated until death occurs in the course of the next weeks or months. In this series there are eight cases in which, from a study of the records, the hemoptysis thus seemed to be the determining factor in the fatal termination. The danger of the retention of infected blood and consequent spread of the tuberculous process is constantly to be borne in mind in the treatment of hemoptysis due to tuberculosis, and it seems highly undesirable to use morphia as a routine as is so generally the custom in these cases. If morphia diminishes the irritability of the respiratory tract and suppresses cough, it may actually do harm by leading to the retention and aspiration of infected material and further spread of the disease. It would seem best, therefore, not to use morphia except for such definite indications as an harassing and unproductive cough and extreme nervousness. It is not, I believe, good treatment for the hemoptysis itself.

#### COMMON SENSE AND CONSUMPTION.

BY JOHN B. HAWES, 20, M.D., BOSTON.

It has been with the greatest of hesitation that I have written this article. The present status of the early diagnosis of pulmonary tuberculosis by the medical profession as a whole, in this country, is so far from what it should be, and so many unnecessary tragedies are caused thereby, that I should consider it in the nature of a calamity, if any opinion that I expressed could in any way be considered as an argument against making the diagnosis of tuberculosis even in a doubtful case.

The superintendents of the four state sanatoria in Massachusetts, whose advice I asked as to whether or not it was wise to consider the question taken up in this paper, felt very much as I did in regard to it. Their opinions are of interest. One of them says:

"I think we can afford to err on the side of over caution for a while longer in giving advice. To my mind, the most important point to impress on diagnosticians, is the importance of several examinations when possible. Before making a diagnosis in a doubtful case, the general practitioner should be impressed with the importance of symptoms in making his diagnosis, when he is not able to make it by physical signs alone."

Another one writes:

"I do not feel that we are admitting any

patients to this sanatorium who ought not to be here. Of course, we always have a few patients in whom, to our mind, the diagnosis is doubtful. We also have a certain per cent. of afebrile, repeatedly negative cases. Although the diagnosis may be doubtful in a few of these cases, I have always felt they should receive sanatorium treatment for a certain length of time. We have seen this class make rapid improvement following a residence of a few months in the sanatorium, so that they have returned to very active lives."

A third one writes:

"I think that many more physicians are able to make accurate examinations, and to consider carefully the presence or absence of tuberculosis in their patients, than was the case four years ago. Instead of hesitating about telling their patients that they have symptoms of tuberculosis, they are more afraid of not being the first to make the diagnosis. If in doubt they do not delay long before calling a consultant. . . . The physicians, however, need to have brought home to them the difference between infection and disease. . . . Furthermore, physicians in clinics somehow fail to remember that an apparently arrested case may have marked physical signs and always will have, although the individual may have established an equilibrium so well balanced between resistance and disease, that he can enjoy fair health and earn a living. . . . Doctors would make fewer errors in diagnosis if they depended more on symptoms, and placed less reliance on the physical signs that may be present. Physical signs without symptoms can usually be ignored. Symptoms, however, with or without physical signs, need careful study. The cause must be found and suitable treatment instituted as early as possible."

Despite this feeling on the part of these men, however, I believe that it is time for us to stop and consider exactly what we mean by the term "consumption," and exactly what it involves, as far as the patient is concerned, when we tell him that he is suffering from pulmonary tuberculosis.

Four years ago I wrote a paper entitled, "Is the Early Diagnosis of Pulmonary Tuberculosis Being Carried Too Far?" At that time I was struck by what I considered the hyper-conservative attitude taken by many physicians in diagnosing tuberculosis. The reasons for this attitude on their part, as they appeared to me at that time, were somewhat as follows:

"Many wrong diagnoses were being made, and as a result, many non-tuberculous patients were sent to sanatoria and health resorts."

"Such patients in whom wrong diagnoses were made and who were sent to a sanatorium, ran a grave risk of catching tuberculosis."

"Furthermore, it was a great injustice and source of hardship and injury to place on any

one who does not deserve what was called the 'stigma of tuberculosis.'"

A few held the view that a diagnosis of tuberculosis is rarely justified unless bacilli are present in the sputum.

"It is not right to 'break up the family' and send away the breadwinner, etc., unless the evidence is positive, and by the term 'positive' is meant 'positive sputum.'"

My own replies to these statements which I made in 1912, differ in certain respects so markedly from the replies which I would make at the present time, as to deserve further comment. To the first statement, that many wrong diagnoses were being made, I gave as my reply at that time that very few wrong diagnoses were made. I gave as evidence the fact that the number of cases at our state sanatoria which were classified as non-tuberculous in that year, amounted to exactly 4%. At the present time, not only is this percentage of cases in our state sanatoria definitely classed as non-tuberculous somewhat larger than it was then, but also our superintendents are coming to feel that it is not purely a question as to whether the patient is free from tuberculous infection, for this in adults would be excessively rare, but as to whether or not he is free from a *tuberculous disease which needs sanatorium treatment*. Looking at the question in this way, my answer would be that there are many wrong diagnoses being made, and that there are many patients in our state sanatoria and elsewhere, who are classified as consumptives, who are undoubtedly tuberculous but are not suffering from consumption needing prolonged sanatorium treatment.

My answer to the second question as to the danger of catching tuberculosis at any institution, is naturally the same now as it was in 1912; namely, that there is no such danger.

To the third question, concerning the amount of injury and injustice done to the patient, by calling him a consumptive on insufficient evidence, my reply in 1912 was that I considered the "stigma of tuberculosis" more a term than a reality, and that no harm, either physical or social, would result to a patient sent to a sanatorium because of a wrong diagnosis. This I would change. My feeling in regard to this matter at the present time is different from what it was four years ago. I believe that the word tuberculosis as a result of our active campaign against the disease, does carry a definite stigma, although perhaps more in the mind of the patient than in those around him. I feel very strongly that the physician who makes a positive diagnosis of tuberculosis bears a very grave responsibility, and that such diagnoses should not be made unless based on good evidence and for excellent reasons.

To the last two statements, in regard to making a diagnosis without a positive sputum, and the right or wrong in breaking up a family without a positive sputum, my answers would

be the same now as they were in 1912, so that no discussion regarding them is necessary.

There is a marked tendency at the present time toward the view that the infectiousness of tuberculosis among healthy, normal adults, is not so great as was supposed. While they do not in any way minimize the danger of the active, open case of consumption to children, they do feel that the intelligent consumptive is perhaps not such a source of danger to normal, healthy adults as was formerly supposed, unless the exposure is a prolonged and intimate one. This point of view is welcomed, I believe, by us all. It has been a great problem as to how long we ought to keep in a sanatorium or similar institution, the patient who is running a normal temperature and pulse, and who is healthy in every way except for certain signs in the lungs, and perhaps bacilli in his sputum. Up to the present, such patients have been urged to remain indefinitely on the ground that, as carriers of the disease, they should not be allowed to mingle with their fellow men, any more than a typhoid or a diphtheria carrier. It is more than probable that, except in rare cases such patients should continue to be kept as long as possible.

This question, then, as to what constitutes clinical consumption, needing treatment for a long time in a sanatorium, is one that should be discussed sanely and calmly. In regard to children, we have come to a fairly definite and satisfactory viewpoint. The time is now past when a child is stamped as a consumptive on the evidence of a positive tuberculin reaction, and a few vague and doubtful signs in the lungs. On the other hand, we no longer hesitate to call a child tuberculous and to institute aggressive treatment, when, in addition to a positive von Pirquet test, there are constitutional signs and symptoms, such as loss of weight and strength, ease of tire, fever, debility, etc., without adequate explanation, even if the signs in the lungs are slight or altogether absent. In other words, in the case of children, we have advanced to the point where we base our diagnoses on the study of the child as a whole, and not on the condition of his lungs alone. In adults, the situation is different and far from satisfactory. This is partly because of the tendency of the American public, medical and otherwise, in whatever it undertakes to swing from one extreme to another, and partly, chiefly perhaps, on account of the vigorous educational campaign that has been carried on during the past ten years. We are now reaching a point where it is dangerous for anyone to have a cough or a cold, or to lose weight, because some doctor is sure to shake his head gravely and say that he suspects tuberculous. Only yesterday, at one of our large Boston clinics, I saw a strong and vigorous young man who had come for treatment of indigestion with no symptoms pointing to his lungs. An eminently qualified physician had made a definite diagnosis of

incipient phthisis. The only evidence I could find to support this diagnosis was that years ago, in Russia, a doctor had told the patient that he had weak lungs and that on examination at the present time, there was slight dullness and prolonged expiration at the right apex. My own examination showed nothing abnormal, and yet this man had been definitely stamped as consumptive and referred to a social service department for investigation and disposal. In another similar case, I could find nothing in the patient's history pointing to tuberculosis, except that his wife was now a patient at Rutland. In the record of his physical examination there was "slight dullness at the right apex?" Confirming (?) this there was an x-ray plate "which shows an active process"! Neither I nor the majority of physicians would consider this sufficient evidence on which to make a definite diagnosis of active pulmonary tuberculosis needing sanatorium treatment, and yet an application had been filed for this patient's admission to a Massachusetts sanatorium.

It goes without saying that this subject must be approached with the greatest caution. Infinitely more harm is done and countless tragedies caused by lack of early diagnosis by the medical profession of today, than is done by making such diagnoses as above mentioned. We must not halt in our efforts to teach physicians and the public how to recognize this disease in its early and curable stages. We must continue our campaign of education and continue it vigorously, so that not only will patients go to the doctors in the early stages, but also doctors will recognize the disease and *be bold enough to say so*, and to institute the proper treatment at the time when it will do some good. In Massachusetts today—and I believe that our standards here are as high as, if not higher than, in any other state in the country in this regard—out of five hundred consumptives in our state sanatoria whom I investigated last summer, nearly *forty per cent.* were told by the first physician whom they consulted, that they did not have consumption, or, worse still, were not told so that they understood it that they *did have* consumption. With these facts staring us in the face, we must be extremely cautious in saying or doing anything that will tend to check the medical profession in its efforts to make early diagnoses of pulmonary tuberculosis.

But at least we can be sane on the subject. As Dr. John L. Morse says in regard to children, "Every child with a cough does not necessarily have consumption, nor does every case of snuffles mean syphilis." Likewise, in adults every protracted cold does not necessarily mean phthisis, nor does everyone who is tired out and who has lost weight and strength have consumption. In the lungs processes characterized by dullness and râles have existed, do exist, and will continue to exist that are caused by pneumonia, influenza and countless other organisms besides the tubercle bacillus. What, then,

should be our standards? What must we demand in the way of evidence before we say that this or that man or woman has clinical, pulmonary tuberculosis? How are we to distinguish between signs and symptoms due to tuberculous infection, and those due to tuberculous disease? In the absence of positive sputum, what evidence must we have before we say that a given area in the lungs, especially if at the base of the lung there are dullness, râles and altered breath sounds, is due to tuberculosis?

These are important and difficult questions to answer. At a recent informal conference of physicians interested in this subject at the Massachusetts General Hospital, Dr. Richard Cabot asked me to state my position in the matter, and to give the evidence I required before making a definite diagnosis of pulmonary tuberculosis in cases without a positive sputum. I told him that I could not give any definite set of requirements, but that each case must be judged on its individual merits. Nevertheless, there are certain general rules which I personally try to follow out. These I would state more or less categorically as follows:

Do not make up your mind beforehand that the case is, or is not, one of tuberculosis.

Do not hurry. In cases where the sputum is lacking or negative, two or three examinations of the patient and many of the sputum are often necessary.

In some cases I am willing to make a positive diagnosis on the history and constitutional signs and symptoms alone, *without signs in the lungs*. Such cases are not uncommon. Likewise, and rather less often, one can safely make a positive diagnosis on lung signs alone without marked constitutional disturbances.

In the vast majority of cases, I demand that there be present both signs in the lungs, generally including râles at one time or another, and constitutional signs such as fever, rapid pulse, subnormal temperature, loss of weight and strength.

Processes at the apices I consider tuberculous until I have proved the contrary; processes at the bases I consider non-tuberculous until the contrary is proved.

A hemorrhage—I do not include as such, minute streaks or flecks of blood in the sputum—in my mind always means tuberculosis until the contrary is proved. This rarely happens. It need not always mean, however, that the patient should give up his work for a long time and go to a sanatorium.

The x-ray gives *confirmatory* evidence which is rarely of great value in diagnosis when taken by itself.

The tuberculin tests I use only very rarely *in adults*. They are of little value and may do harm.

Observations of temperature and pulse, taken at home three or four times daily for three or four days, give evidence of the greatest value.

The most important evidence, and probably

most neglected, is that obtained from a careful and detailed study of the patient, his family history, habits, surroundings and occupation.

To sum up then, the diagnosis of early pulmonary tuberculosis or clinical consumption requires patience, perseverance, boldness, and above all, *common sense*.

The physician must remember always that he is dealing with a *human being*, and not merely a set of lungs normal or abnormal.

While the diagnosis may justly be made on signs in the lungs alone, or on constitutional signs alone, in the vast majority of cases there is a combination of both.

It is usually the careful study of the patient's history, his habits, surroundings, occupation, and the constitutional signs and symptoms that he presents, which is of paramount importance and which is most often neglected.

Do not forget that, in doubtful cases, it is possible and often wise, to institute proper treatment and to obtain the patient's fullest cooperation by a few minutes' plain talk, without definitely stamping him as a consumptive.

But above all things, remember that, from the patient's point of view, it is better to be "safe than sorry," better to undergo a few weeks or months perhaps unnecessary treatment as a "lunger" (and to gain physically by so doing), than to linger along in false security until the chances of cure are gone.

## SPRAINS AND SPRAIN-FRACTURE OF THE WRIST JOINT.

BY A. C. BURNHAM, M.D., NEW YORK.

THE frequent use of the x-ray during recent years has caused a considerable modification in the diagnosis and treatment of injuries about the joints, but it requires only a short experience in any surgical clinic to demonstrate the frequent errors of omission and commission which are associated with the diagnosis of so simple an injury as sprained wrist.

In the discussion of the injuries with which a sprain of the wrist joint may be confused, there are three general classes of injury which must be differentiated and which may be included under the general terms of sprain and fracture. Even this classification requires further definition, as the terms "sprain" and "sprain-fracture" have been loosely used and are often classed together under the general term of "sprains."

The term "sprain" should be limited to the partial or complete rupture of the ligaments about a joint without luxation of the bones. Should subluxation occur during, and as a part of the mechanism causing a sprain, the condition is essentially a sprain and should be considered as such. The tearing of the ligaments

may take place at any part of the ligament and may be so mild as to cause only a partial rupture of the fibres; or it may be severe enough to cause a complete division of the injured ligament.

If the fibrous band is so firm, however, that a portion of the bony attachment is torn away before the ligament ruptures, the injury is said to be sprain-fracture, and this term has been enlarged to include the tearing away of a portion of bone at the insertion of a tendon by a force which is exerted in such a manner as to tend to tear away the tendon from its bony attachment. The condition of sprain-fracture is, strictly speaking, a fracture, and while it may be conveniently described as a sprain-fracture, it represents pathologically a fracture and is related to a sprain only from a clinical point of view, because of the great difficulty of differential diagnosis.

The ordinary type of fracture is of interest in this connection because, in the region of the wrist, gross fracture is so frequently overlooked. This is more especially true about the wrist joint than it is about other joints,\* and because of its special surgical significance must be discussed in detail.

\*Omitting from the discussion the cases of Colles' fracture with marked deformity which reach the surgeon after several weeks or months of treatment as "sprain," there still remain a considerable number of cases in which the x-rays show a distinct fracture, and which lack most of the classical text-book symptoms upon which the student is supposed to base his diagnosis of fracture.

Ross and Wilbert, in 1902, called attention to the frequency of fractures in "so-called sprains" in various joints, and more recently Ross and Stewart (1912) have made an exhaustive experimental study of sprain-fracture and have demonstrated that many, if not all, luxations and subluxations are associated with sprain-fractures or gross fracture. Stern has collected a number of cases of joint injury treated for a considerable period as sprain, in which subsequent examination clearly demonstrated that the original injury had been a fracture. It has been claimed that ninety per cent. of the "sprains" that are referred to the radiographer show fracture.

The writer has limited this paper to the discussion of injuries about the wrist joint, because it is exactly in this joint that most of the injuries occur, and, consequently, in which careful examination will cause most of the errors of diagnosis to be brought to light. The bony prominences about the wrist are freely palpable, and, as x-ray examination is comparatively simple, it lends itself more easily to examination and study than any of the other large joints.

Given then a "sprain" of the wrist, in which the classical symptoms of gross fracture (crepitus, false point of motion and bony deformity)

are slight or absent, how are we to differentiate the various types of injury to which the so-called "sprain" may be due? True sprain is associated with the history of an injury which is followed, after an interval varying from a few minutes to several hours, by swelling and pain. The region of the joint is usually tender, but there is special localized tenderness over the ligament injured, and this may be greater or less, according to the extent of the injury. The motions of the joint which put this ligament on the stretch are very painful and the joint may be swollen, due to the accompanying effusion into it. The relation of the location of the trauma, as given in the history, and the point of maximum tenderness, as found by examination, is most important. A fall on the palm cannot possibly cause an injury to the dorsal ligaments of the joint, and the occurrence of acute tenderness on the dorsum of the wrist after such a fall should arouse suspicion of some other injury. In the same manner a fall on the dorsum of the hand, which may cause a sprained wrist, should not be the cause of tenderness along the palmar aspect of the wrist.

In many of these cases the point of maximum tenderness is at or near the attachment of the ligament, and in such patients there may be a sprain-fracture. From cadaver experiments, Ross and Stewart decided that the ligaments were often stronger than the bone at the points of their attachment. In some cases the small detached portion of bone may be felt beneath the finger.

Gross fracture, as has been stated before, is frequently mistaken for sprain. Its detection is usually simple and the diagnosis may be made with the expenditure of a little time and with very slight discomfort to the patient. In the type of fracture commonly confused with sprain, swelling is practically always present, while deformity is absent, or is so slight that its detection is difficult or impossible. Ecchymosis is present, but usually late in making its appearance. Tenderness by direct and indirect pressure is always present, and is most important for purposes of diagnosis. Crepitus and false point of motion are absent or obtained with difficulty. When present they are elicited only by unjustifiably painful manipulations. Measurements usually give no information, the bony prominences retaining their normal relations. Function is usually limited, but in a few cases there is a surprising preservation of the normal movement of the wrist even in a fracture with considerable displacement.

We have, then, the same symptoms associated with the non-deforming fractures about the wrist joint as are found in sprained wrist, and it is this similarity which causes the confusion of these two conditions. This confusion is for the most part absolutely unnecessary, even in the absence of radiographic examinations.

The symptoms of sprain are pain, loss of function, swelling, tenderness and ecchymosis.

The symptoms of fracture near the joint are exactly the same, and it is only by the most painstaking examination that the two conditions may be differentiated. The differential diagnosis is based almost entirely on the character and location of the local tenderness. In sprain the tenderness is most acute over the torn ligament, and if a satisfactory history is obtainable it will be noted that the tenderness is located over some part of the ligament which was stretched by the force of the trauma. By the indirect method, tenderness is elicited by the motion of the joint which makes the torn membrane tense. This should correspond with the movement described by the hand in the causation of the sprain. Thus forcible dorsal flexion may cause a laceration of the anterior ligaments of the wrist joint (sprained wrist), and in such a case there should be direct tenderness over the anterior ligaments, and hyperextension (dorsal flexion) should cause pain referred to the anterior aspect of the wrist joint.

The same symptom (tenderness) is present in fractures near the joint, but its character and location are so distinctive as to make possible a diagnosis almost beyond question. The pain of fracture has been described by Skillern as "wincing" and by Stern as "pencil tenderness." Both names are descriptive of the type of tenderness found. If the injured bone is palpated with the finger end, or better, with the rubber end of an ordinary lead pencil, a peculiarly acute type of tenderness is elicited at the point of fracture, which almost always causes the patient to wince perceptibly. If the bone is palpated wherever its surfaces are superficial, this area of "wincing" tenderness may be mapped out and will almost always correspond definitely with the line of fracture, failing only in those cases in which there has been a trauma of the bone, due to direct violence. The duration of local tenderness in fracture is usually three or four weeks or longer, in contradistinction to sprains, in which the tenderness usually lasts only a few days to one or two weeks. The location of the "wincing" tenderness in fracture is important. Evidently it must occur not over the joint, but over the bone at the point of fracture and, characteristically, it occurs some distance from the point of trauma, in a location where tenderness would not be present in the absence of fracture.

The search for local tenderness in injuries about the wrist joint is extremely important and cannot be too greatly emphasized. Once the examiner is trained to search for this type of tenderness, the diagnosis of obscure injuries about the wrist (and other joints) becomes comparatively easy, and the number of cases of "sprained wrist" shows a corresponding decrease. If we suppose, as above, that forcible dorsal flexion has caused an injury to the wrist and a line of wincing tenderness is found about one-half inch above the wrist, there being, at the same time, only slight or moderate tenderness

over the ligaments, it is evident that the lesion is not a sprain but an injury to some structure above the wrist joint. Thanks to the x-rays, we now know that these cases practically all represent linear fractures, with little or no deformity.

Radiographic examination is important in these cases, but care should be taken to interpret the plates correctly. In the presence of symptoms as described above, the fracture is usually easily detected, but there is a considerable number of cases in which the parts must be radiographed in several directions before the line of fracture can be made out. Cases occur in which repeated skiagrams fail to show fracture, but which show typical callus several weeks later. In order to emphasize the unreliability of the x-ray and the comparative importance of localized tenderness, I quote verbatim from Skillern, whose opinions I heartily endorse: "The diagnosis of an injury to the forearm should always be made by careful clinical investigation. It is a great mistake in more than one way to depend exclusively upon the skiagram. A skiagram must be considered merely as one of the many signs of fracture. There are two factors which will diagnose 90% of fractures of the forearm clinically. One is a thorough understanding of the mechanism obtained from a careful history, and the other, "wincing" tenderness. It has been shown that a given mechanism is apt to produce a certain fracture. This, in turn, indicates where to examine for "wincing" tenderness. When the site of fracture is reached, moderate pressure with a finger tip causes the patient to wince; he screws his face up and involuntarily withdraws his arm. This is almost pathognomonic of fracture."

It is impossible within the limits of this paper to do more than indicate the different varieties of fracture which are frequently confused with sprained wrist. Fractures of the lower end of the radius are the most frequent. Of these, Colles' fracture, with slight or no displacement, is probably most often seen. Longitudinal fracture of the lower end of the radius, oblique fracture (Barton's) of the lower and outer aspect of the same bone and T- and Y-shaped fractures are not uncommon. Fractures of the tip and lower end of the ulna are less common, and fractures of the scaphoid and semilunar bones are probably frequently seen but rarely diagnosed in the absence of the x-ray. Of especial interest in this connection are green-stick fracture and separation of the epiphysis in children. These conditions frequently are negative to x-ray examination and depend for their diagnoses entirely upon the history and localized tenderness. Luxation of the epiphysis without permanent displacement is frequently mistaken for sprained wrist. It is sometimes referred to as epiphyseal sprain. However, in most cases, epiphyseal separation consists of a combination of separation and

fracture of the adjacent bone. Infectious arthritis and synovitis may simulate sprained wrist, but the history and progress of the disease soon makes the diagnosis clear.

The treatment of sprained wrist depends somewhat upon the location of the injured ligament. When the dorsal or lateral ligaments are injured, a satisfactory dressing consists of strips of adhesive plaster crossing at the back of the hand and extending from the metacarpophalangeal joint to about the mid-forearm, being so applied as to limit flexion at the wrist. When the anterior ligaments are injured, which occurs only very rarely, rest and massage is the treatment of choice.

When the condition is such that the injury cannot be differentiated from fracture, it is better to consider the lesion as a fracture and to treat it accordingly. A plan which has been found satisfactory in the treatment of fractures of this type (fractures near joints without gross deformity) is fixation combined with early massage and passive motion. As such treatment is equally beneficial in sprained wrist it merits description in some detail. The wrist is fixed by means of a posterior splint extending from the knuckles to the upper third of the forearm and the patient told to return daily for massage and passive motion. The massage is begun on the second day with very gentle manipulations, the arm being stroked gently and superficially from the fingers toward the elbow, according to the method of Lucas-Championnière. Care should be taken to cause little or no pain, and to massage constantly in the same direction. As the pain diminishes, the fingers, and later the wrist joint, should be moved, at first passively and later actively, the amount of movement depending upon the subsidence of the pain and swelling. Usually ten to fifteen minutes' massage during the first day is sufficient, but the period may be lengthened to twenty-five or thirty minutes after a few days. Under this treatment there is a rapid subsidence of tenderness and swelling, if the case is sprain, but should fracture be present the improvement is more gradual and the tenderness persists even after several weeks.

In conclusion, attention should again be drawn to the importance of the early recognition of fractures near the wrist joint, and emphasis should be placed upon the fact that "sprained wrist" is a diagnosis which often serves as a cloak to hide the ignorance of the physician. The belief that "a bad sprain is worse than a break" is based upon the fact that a "bad sprain" is usually a fracture, and it is worse than a break because it is treated as a sprain and neglected as a fracture.

## A STUDY OF PEPTIC ULCER FROM THE DIAGNOSTIC POINT OF VIEW.\*

By ROSCOE H. PHILBRICK, M.D., NORTHFIELD, MASS.

IN this paper I have grouped gastric and duodenal ulcer under one heading, that of peptic ulcer, since physiologically, clinically, and pathologically, the first part of the duodenum is identical with the stomach.

In browsing through the literature, which is voluminous, I was surprised at the alleged frequency of ulcer. Mumford has stated "that of all the lesions giving rise to digestive disorders, ulcer of the stomach and duodenum holds the first place."

W. H. Welch estimated that about 5% of mankind suffer from gastric ulcer, figures founded on findings at autopsy of open or cicatrized ulcers. Some writers place the percentage much lower, while others claim much greater frequency. Mumford believed that the true percentage was probably higher than Welch's estimate.

Careful analysis shows that gastric ulcer is as common in men as it is in women, though duodenal ulcer is perhaps more frequent in males.

The most frequent age given is twenty to forty years, but an analysis of a long series of cases shows that ulcer is more liable to occur between forty and fifty. Frequently ulcer patients are over fifty, but the records show few cases under twenty. Ulcer has been found in young children.

The conjugal condition, occupation and family history seem to play little part, but ulcer seems to be a trifle more frequent in the negro race; and if reports from Teuton sources are correct, the Germans seem more prone to ulcer than other nationalities.

In looking over the previous history of ulcer cases, in a few instances there is a definite history of trauma. It is generally conceded that burns may lead to ulcer, especially of the duodenum, but I could find no satisfactory explanation of the circumstance. There is no doubt that arteriosclerosis, by predisposing to thrombosis, plays some part in the pathogenesis of ulcer. Syphilis may have a place in the etiology through the production of a local specific endarteritis. Endocarditis may give rise to embolism and should be considered. One investigator found, in a series of ulcer cases,

\* Read at a meeting of the Faculty of the Medical School, Jan. 11, 1915.

valvular disease present in 9%. It is agreed that any chronic disease which lowers the vitality, such as tuberculosis, increases the liability to ulcer. Alcoholism may predispose. A certain percentage of cases give a previous history of chlorosis, and in a very large majority there is a definite history of "stomach trouble" persisting for months before the onset of symptoms suggesting ulcer. The majority describe it as "indigestion," as shown by discomfort after the ingestion of certain articles of food, eructations of gas and pyrosis. A study of peptic ulcer shows that the previous history of "stomach trouble" verges into the present illness without any line of demarcation. In other words, if we go back to the onset of dyspeptic symptoms, we shall know when the ulcer or ulcers started.

How do peptic ulcers form? This is a much debated question. W. J. Mayo seems to lean toward the theory of mechanical injury plus excessive acidity, while Leube says "A weak constitution, chlorosis, and anemia predispose to ulcer." Riegel states that local trophic changes take place, necrosis ensues and the dead tissue is naturally digested by the gastric juice. He believes that hyperchlorhydria (if present) is a manifestation of abnormal irritability on the part of the secretory glands of the stomach. His is the most reasonable hypothesis from my point of view.

The cardinal symptoms of ulcer are pain, vomiting and hematemesis. In Greenough's and Joslin's series of 187 cases, 96% had vomiting, 92.5% had pain and 79% had hematemesis. Pain is the predominant subjective symptom. In 50% of a series of 82 cases, pain was the chief complaint. In 47.7% "stomach trouble," dyspepsia, or vomiting were the symptoms for which relief was sought. In only 6% was the vomiting of blood voluntarily mentioned.

Only a few of the cases in this series could be termed acute, the large majority being examples of chronic ulcers existing from two months to twenty years. The usually accepted time limit, however, is from three to five years.

Pain is usually the first indication of the existence of ulcer, and is its most constant and distinctive feature, although, as we all know, pain is sometimes difficult to estimate. In ulcer cases it is usually epigastric, sometimes referred to the back, sometimes to the left shoulder blade, and rarely to either hypochondrium. In passing, it is a mistake to believe that the location of pain gives any clue to the site of the ulcer, for in 27 cases where the location of the ulcer was determined at operation or autopsy, the site of pain seemed to bear no relation to the location of the ulcer.

The pain is usually severe in character, though it may not exceed that of hyperchlorhydria; it is rarely continuous and, if so, usually denotes some complication such as localized peritonitis, adhesions or hyperchlorhydria. Pain is variously described as sharp, dull, aching, burn-

ing, colicky, gnawing or grinding, also as cutting or tearing. It is often influenced by position, usually increased by eating, but may be relieved or be entirely independent of food. Gerhardts makes the point that, while the patient would like to eat, he is often afraid to do so on account of the suffering which may ensue.

Vomiting is about as common a symptom as pain. In most cases it is frequent, in a few constant, and in others periodic. In a certain number of cases it is only occasional, following paroxysms of pain, or the ingestion of certain food. The quantity of vomitus varies, but is profuse only when there is pyloric obstruction or hypersecretion. Analysis of a series of 22 cases shows there is less liability to vomiting and pain when the ulcer involves the lesser curvature. In Howard's series pain was practically constant, except in ulcer of the pylorus or lesser curvature. Vomiting is also less frequent where ulcer is duodenal. Indeed it is stated by Moynihan that pain is the only symptom of duodenal ulcer. Ulcers involving the greater curvature or either orifice produce more constant vomiting.

Hematemesis occurred in 76% of 82 cases. Two-thirds of these had coffee ground vomitus, and one-third bright red. Of course the coffee ground vomiting occurs when the blood stays in the stomach long enough to be acted on by the gastric juice. Hematemesis often occurs more than once, and sometimes gives immediate relief to pain and vomiting.

Severe hemorrhage from an ulcer almost invariably gives bloody or tarry stools. This may not be accompanied by hematemesis when the ulcer is in the duodenum or near the pylorus. Patients are not reliable observers as to melena. The color of the blood varies according to the quantity, freshness and length of time taken to pass through the intestinal tract.

Nausea is noted in a relatively small percentage of cases, which seems natural, as vomiting is generally the result of pain, and is an attempt on the part of the stomach to get rid of irritating material. It does not usually require much effort.

There is almost invariably discomfort after eating, eructations, pyrosis, headache, palpitation and meteorism. This may be due to chronic gastritis, or attendant hyperchlorhydria.

Patients with ulcer are usually constipated, probably on account of the small amount of solids taken and retained. On the other hand, a small percentage of cases show looseness if not actual diarrhea.

There is almost invariably a loss of strength and some loss of weight, due to pain and inability to eat. Sometimes the loss of strength is due to hemorrhage. Marked loss of weight suggests cancer but it must not be forgotten that pain, coffee ground vomitus and marked loss of weight can all be present in benign ulcer of the stomach.

Tenderness is the least important of the physical signs. Its absence or presence is responsible for many errors in diagnosis. In a series

of 187 cases, it was noted in 69.5%, and the degree varied from one extreme to the other. It is usually located in the epigastrium, but may be in either hypochondrium, in the right iliac fossa, or the umbilical region.

Authorities seem to differ widely as regards demonstrable mass or resistance. In Osler's and McCrae's series, it was noted in three-fourths of the cases. In Howard's series in about one-third. Gerhardt says it may be found in any one of four conditions, namely, (1) Thickened base and hard margin of the ulcer itself; (2) functional hypertrophy of musculature; (3) localized exudate or abscess from perforation; (4) adhesions between neighboring organs.

It is estimated that the stomach is dilated in 20% of ulcer cases. Dilatation would signify pyloric obstruction; directly from the ulcer, resulting scars, or perigastric adhesions; or indirectly, from pyloric spasm.

The determination of free HCl is of value in the analysis of gastric contents, but too much importance should not be attached to it. In Howard's series, analysis of gastric contents, after a test meal, showed HCl diminished in 26%, practically normal in 27%, and increased in only 18%. It is valuable to note the contrasting results in a series of cancer cases where free HCl was absent in 92%. The relative infrequency of hyperchlorhydria in ulcer cases, as shown by analyses, is somewhat contrary to the generally accepted belief, but it fits in nicely with Riegel's explanation.

Röntgenologists are, of course, enthusiastic over the advantages of their method of diagnosis and claim the ability to diagnose a large percentage of ulcer cases. Doubtless, in many instances, regional x-ray photographs, after the ingestion of a bismuth soup, would show characteristic depressions in the gastric or duodenal mucosa as well as the cicatricial contraction which follows extensive ulcers.

There is but one other laboratory test of value and that is the finding of occult blood in the stools or in the gastric contents.

The alterations in the blood are those of secondary anemia due to hemorrhage.

The urine shows nothing of interest.

Fever is present in about one-third of the cases, but does not exceed one or one and one-half degrees. It is usually not continuous and, if irregular, signifies a complication.

Of 76 cases collected by Howard, 5 had definite pyloric obstruction and two had duodenal stenosis.

In Greenough's and Joslin's series, there were 7 fatalities from hemorrhage and in Howard's cases 7.

Perforation is rather rare, Howard noting 6 cases out of 82.

Parotitis is not a rare complication. I suppose it is due to lowered resistance to bacterial invasion.

There may be almost any associated condition.

As regards diagnosis, it is not easy. Sava-

reault estimates that 20% of ulcers do not produce symptoms. M. C. Millet believes that every other case is undiagnosed in life.

Osler says, "The condition may be met with, accidentally, post-mortem. In other cases again, for months and years the patient has had dyspepsia, and the ulcer may not have been suspected until the occurrence of sudden hemorrhage."

H. D. Niles, in a series of 75 cases, found that in 88% the initial symptoms might easily be attributed to any mild digestive disturbance. In his series the average time from the first symptom to operation was 8 years. He believes that if a stomach ailment is of long duration, or recurs without apparent cause, it is probably due to ulcer rather than to a functional disturbance.

Moynihan says that, "hyperchlorhydria is the medical term for the surgical condition called duodenal ulcer."

The recognition of duodenal ulcer is probably more difficult than that of gastric ulcer, for there is usually less symptomatology. The patient usually states that attacks of pain have recurred for years past; sometimes daily, perhaps only once a year. During intervals patients are usually perfectly well, although they sometimes complain of persistent acid dyspepsia, or burning distress some hours after meals, often at night. Relief is obtained by taking food, or some simple antacid, like soda bicarbonate. With duodenal ulcer there is seldom any vomiting, and the physical signs are usually negative. There may be tenderness during the attack or immediately after.

In gastric ulcer troublesome dyspepsia is more likely to be persistent between attacks. The pain is usually of the same character, but is more liable immediately to follow eating. Following a test meal the stomach contents may show occult blood. In duodenal ulcer occult blood might be found in the feces, but seldom in the stomach contents. There is usually more tenderness in gastric ulcer.

In general it is very difficult to differentiate between ulcer of the duodenum and ulcer of the stomach, and it is hardly necessary. It is far more important that we recognize or differentiate between a functional disturbance of the stomach, such as acid dyspepsia and ulcer, no matter whether gastric or duodenal.

There is no single symptom or laboratory test upon which we can rely. We must depend largely on groups of symptoms, and, where after careful study the diagnosis is doubtful, resort to exploratory laparotomy.

Where the diagnosis rests between ulcer and cancer, we must remember that practically all cancer cases show absence of free HCl, accompanied by loss of appetite, and rapid emaciation, symptoms most unusual in ulcer. Differentiation is not ordinarily difficult.

It is more difficult to rule out attacks of hepatic colic. There are the same recurring seizures, possibly the same chronic dyspepsia, and in the

interval the patient is perfectly well. However, the pain is different in character, being colicky, with remissions and exacerbations coming on more suddenly and ceasing more abruptly than in ulcer. It usually starts in the epigastrium but radiates quickly to the right costal border, and around into the back underneath the right shoulder blade. The pain is not relieved by food, alkalies or vomiting. Patients with biliary colic often feel chilly, sweat profusely, are almost invariably nauseated, and vomit frequently.

In about half the cases, jaundice follows the attack. The tenderness and rigidity following the attack is at the right costal border. Occult blood does not occur in the feces unless complicated by some other condition.

If we bear in mind the frequency of peptic ulcer, and are diligent in the study of our chronic "dyspepsia" cases, we may be spared humiliation and remorse. Undoubtedly in many instances ulcer is the true diagnosis.

## THE FIRST CASE IN WHICH ABDOMINAL SURGERY WAS SUGGESTED FOR THE RELIEF OF EPILEPSY.

BY HALE POWERS, M.D., BROOKLINE, MASS.

*Second Assistant Visiting Physician for Diseases of the Nervous System, Boston City Hospital; Assistant in Neurology, Tufts College Medical School.*

WITH NOTES ON THE OPERATION.

BY FRANK H. LAHEY, M.D., BOSTON.

*First Assistant Visiting Surgeon, Boston City Hospital; Assistant Professor of Clinical Surgery, Tufts College Medical School.*

ON August 7, 1913, there was published in this JOURNAL an article entitled *The Role of Gastric and Intestinal Stasis in Some Cases of Epilepsy*. This was a report of what was probably the earliest employment of the bismuth x-ray in the study of epilepsy, and in conclusion the writer stated that he felt reinforced in his belief that in so-called idiopathic epilepsy the essential lesion was not in the nervous system. All assertions made in that article have since then been verified by others. In one of the cases, after consultation with Dr. Frank H. Lahey, it was decided to advise the patient to submit to an abdominal operation, not for the cure of constipation, but for the relief of the epilepsy. Sufficient time having elapsed, we now feel that the case may be reported.

The following description of the case and the illustrations are from the original article:

had epilepsy. His father's grandparents were first cousins. He is a brunette like his father's family. At fifteen he had measles and shortly afterward his first epileptic seizure. The attacks have occurred about once in two or three weeks since then. They are preceded by tremor of the facial muscles, sometimes twenty-four hours beforehand. They are of grand mal type, lasting a few minutes and followed by stupor for a half hour and drowsiness for the remainder of the day. Examination was negative except for a fine tremor of the outstretched fingers. Salt-free diet and sodii bromidi gr. x t.i.d. were prescribed. Later, because of a bromide rash, Bromotone gr. v t.i.d. was prescribed. Under such treatment there was no change in the severity or frequency of the attacks. On Oct. 9, 1912, when first seen by the writer, he reported that while in New Hampshire during the summer he had been very much worse. He was then instructed in abdominal exercises and advised to use laxatives more frequently. On Jan. 27, 1913, he reported only one attack since the last visit in October, and that was on Christmas Day after dinner. On Jan. 28, 1913, the first radiograph was taken. Plate I shows the stomach much dilated and extending down into the pelvis. Plate II, after five and one-half hours, however, shows the stomach quite empty and the bismuth meal occupying part of the ileum and the colon as far as the splenic flexure. The transverse colon is far below the iliac crests and the hepatic and splenic flexures are thereby much accentuated. Plate V, after forty-eight hours, shows the transverse colon still occupied by the bismuth meal, which would be normal after twenty-eight hours. There is none in the caecum or hepatic flexure and this points to the very low transverse colon as the cause of the stasis. Plate VI, after fifty-four and one-half hours, shows the descending colon and rectum still full, which would be normal after thirty-two hours. *In this case the possibility of relief through surgery suggests itself and this will be attempted with the patient's consent.*

The patient at that time was a typical epileptic as described in the text-books: heavy in body and mind, unfit for any employment and discouraged. After eight years of treatment by the various bromides and by the salt-free diet, the milk and vegetable diet, *et cetera*, he had not enough confidence left in medicine to begin another course of treatment, and, after the radiographs were taken, he did not return to the hospital until September, 1914. He was then willing to submit to an operation, and on Sept. 17, 1914, a colectomy was performed by Dr. Lahey. After his recovery from the operation, he was unwilling to be placed upon a régime, but ate everything that he cared for and, after his old habit, he bolted and gormandized. Notwithstanding this, he remained free from attacks until Dec. 14, 1914. In March, 1915, he had another attack. He was then willing to submit to treatment and was placed upon a diet list published by the writer in the *Interstate Medical Journal* for December, 1914, and for some time in use in the Boston City Hospital. This diet is not vegetarian or salt-free and in it the abuse of milk is avoided. It may be briefly described as one excluding fried food, fresh white bread, pastry, beans, milk, except in moderate quantities only with meals, and uncooked fruit except oranges, figs and dates. The diet list bears a footnote directing the patient to chew thoroughly, eat slowly, never hurry after eating, never to eat too much and not to eat

"CASE 2. Male, age 23, occupation clerk. First entered clinic Feb. 15, 1911. Two paternal uncles

Case II, Plate I

Case II, Plate II, 30 hours

Case II, Plate III, 5 1/2 hours

Case II, Plate IV, 48 hours

Case II, Plate V, 29 hours

Case II, Plate VI, 54 3/4 hours

for pleasure. It is based upon the facts that nearly all epileptics are bolters, nearly all are constipated and nearly all eat too much, especially of the prohibited articles. Its rationale was discussed in the article in which it was first published.\* The patient, on resuming treatment, was first given:

R Sodii bromidi 5iiss  
fl. ext. cascara 5v  
aq. ad 5iv  
Sig. 5i t.i.d.

R Thymol gr. iv before meals.

R Sodium bicarbonate gr. x when having flatulence or abdominal pain.

The bromide was discontinued June 13, 1915, and the sodium bicarbonate and cascara were discontinued in July, 1915. He has had no medicine for epilepsy since then. He has remained more than a year without an attack and without vertigo or any so-called epileptic equivalent. During that time he has been in business and he is more keen and energetic than the average individual. Moreover, his work is indoors and he has not been compelled "to find some active out-of-door pursuit." No discomfort has resulted from the operation except that he has two unformed movements daily.

We do not conclude that colectomy should be done in every case of epilepsy or in every severe case. While the colectomy undoubtedly assisted in the treatment of this case, perhaps the patient would have been relieved without the operation, had he been willing to submit to the régime upon which he was finally placed. This régime without the operation has produced equally good results in other cases. No case should be submitted to colectomy merely because it has failed to improve under bromides and a vegetarian diet. When constipation is manifest and gives way to non-surgical treatment the writer does not consider it essential to have serial radiographs made and prefers not to do so, for the reason that this procedure makes it necessary to suspend treatment for two days, sometimes causing a series of attacks. The x-ray should be used when no history of constipation can be obtained and when surgery is contemplated. Two years ago, with the cooperation of Dr. Ralph D. Leonard, radiologist, the writer undertook to determine whether or not incompetency of the ileocecal valve were a factor in epilepsy, thinking that regurgitation into the ileum might induce the attacks. But in several cases the valve was found to be competent and distention of the caecum and colon by the high bismuth enema was followed by attacks. Therefore this work was not continued. In another of our cases in which colectomy was done, the patient became maniacal a few hours after the operation and forty-eight hours thereafter died of exhaustion. Operation in this case was resorted to because the patient would never continue

treatment faithfully, was growing worse and was subject to attacks of automatism in which he endangered himself and others. Not infrequently do epileptics present symptoms of chronic appendicitis, with or without colitis, and these cases the writer believes should be submitted to whatever operation is indicated, as the first step in their treatment.

In conclusion I would urge conservatism in the employment of colectomy in epilepsy because, in my own experience, equally good results have been obtained without it, when the full coöperation of the patient and his family have been obtained; and because the too frequent resort to colectomy would eventually bring this useful measure into disrepute. It should be reserved for cases in which rational non-operative treatment, with painstaking attention to detail, directed toward the relief of the intestinal condition, has failed, and for cases in which, because of mental enfeeblement, or for other reasons, the coöperation of the patient in his treatment can not be secured.

#### NOTES ON THE OPERATION, BY DR. LAHEY.

It is the writer's wish to endorse what has been said by Dr. Powers in relation to conservatism in the employment of colectomy in epileptics. Regarding its curative value, only time and a number of cases can tell.

The operation itself is not an extremely difficult one, nor is it extremely dangerous. Its immediate danger arises from shock (of this there has been none in cases done by the writer) and the danger of leakage which always goes with an intestinal anastomosis. In the case cited in this paper the convalescence from the operation was even easier than from an interval appendectomy. About eight inches of the ileum, all of the caecum, ascending, transverse and descending colon were removed and the ileum anastomosed into the rectum. The caecum was extremely large and its walls considerably thinned.

As to advising the operation in epileptics, my position has been to tell the patients and their relatives frankly that there is a definite danger in the operation (although I believe it is but slight with careful technic) and that I can do the operation only if they understand that it is a last resort, and that too few cases have been done to do more than undertake it as a possible measure of relief and by no means an assured one.

In the few cases seen by me, the operation has not been considered by the patients or suggested by Dr. Powers unless they were in such condition that they were a burden to themselves and friends. In such cases it is my opinion that it is justifiable to submit them to the operation of colectomy, unproven as it is.

\*Powers: "Some Observations on Diet in Epilepsy," Interstate Medical Journal, St. Louis, December, 1914

## PROLAPSUS ANI IN ADULTS.

BY T. CHITTENDEN HILL, M.D., BOSTON.

*President, American Proctologic Society; Instructor in Proctology, Harvard Graduate School of Medicine; Surgeon, Rectal Department of the Boston Dispensary; Proctologist, Out-patient Department, Carney Hospital, Boston.*

THERE are two varieties of prolapse of the rectum that can be recognized by one familiar with these conditions. As the treatment of each differs essentially, a few words about them both will not be out of place here. The first variety is prolapsus ani or prolapsus mucosae recti. A protrusion of two inches is about the extreme amount found in this condition, and is, therefore, a point of importance in determining with which variety one is dealing. The protrusion of the mucous membrane not infrequently is limited to one side, but as a rule, both sides are protruded.

The other form of prolapse is a protrusion in which all of the coats of the bowel, including mucous, sub-mucous, muscular and, in certain aggravated cases, even the peritoneal investments, are prolapsed. This latter state is more commonly referred to as procidentia recti. It may, perhaps, be best described as a turning inside out of the lower portion of the bowel. Thus we see that it is very desirable that these two distinct varieties, which are often loosely classified together, should be clearly borne in mind, as the treatment of each is decidedly different.

In this paper I wish to confine myself to a discussion of prolapsus ani and describe a simple operation which effects a permanent cure. There are two principal reasons for calling attention to this subject.

1. Practically all cases of procidentia are the result of neglect or improper treatment of what was in the beginning a simple form of mucous membrane prolapse. The mucosa is attached to the muscular wall of the rectum by a loose network of connective tissue, which normally permits a certain degree of mobility of one coat upon the other. If this mobility becomes exaggerated, whether from a general laxity of the tissues, loss of tone of the sphincters or the absence of fat in the ischio-rectal fossa, an eversion of mucous membrane takes place. If surgical intervention is not instituted at this stage the next step may be a slipping out of the rectum in its entirety. Therefore early prophylaxis should always be insisted on.

2. Prolapsus ani occurs at all ages. It is especially common in young children, but they seldom require operative treatment. It is frequently seen in middle life, and among elderly people it is often their chief infirmity. I believe it is a great mistake to advise any of these patients, even the decrepit and aged, to be satisfied with palliative treatment, which never, at

the best, affords much relief, when a safe operation can be easily performed under local anesthesia. Several of my patients have been over eighty years of age and would have been considered poor surgical risks had general anesthesia been required, but, without exception, they made quite as rapid recoveries as do much younger subjects. The importance of relieving the easily remedied defects of old age cannot be overestimated. Many of these neglected cases of rectal prolapse become practically confined to the bed or at least must assume the recumbent position the greater part of the time on account of the protrusion, which recurs when standing or walking about. Such inactivity is a severe tax upon their vitality, and will inevitably lead to an increase in the normal mortality of advanced life.

Various procedures have been recommended and are used in the treatment of this condition. Caulterization by applications of nitric acid or by linear burning with paequin is unreliable and, therefore, should not be employed. The removal of elliptical strips of the redundant mucous membrane with the clamp and cautery will often give satisfactory results, but it does not remove all the pathology. There are technical difficulties, as the clamp is a clumsy instrument to use without thorough division of the sphincters, a procedure distinctly harmful in this class of cases. Moreover, the realization that a red hot iron is being used distresses nervous patients unless done under full surgical anesthesia. Whitehead's operation is essentially a circular excision of the prolapse followed by suturing the mucous membrane to the skin at the anal margin. My objections to this method are the loss of blood attending it, the length of time consumed and the slow and irregular healing which often ensues.

The following operation I have found best adapted for cases of prolapsus ani. The main features of this method<sup>1</sup> were first advocated and practised by the late Mr. Goodsall, at St. Mark's Hospital for Diseases of the Rectum, London, Eng. With certain modifications, I have now employed it with entire satisfaction for twelve years. Mr. Goodsall did not incise the mucous membrane at the muco-cutaneous junction, nor did he excise the prolapse. He applied the ligatures in the ingenious manner I shall presently describe, after which he recommended that "As soon as all the ligatures have been tied, the strangulated parts should be returned into the rectum and kept in position by a plug of cotton wool soaked in twenty per centum solution of cocaine." On the other hand, my practice has always been first to separate the mucous membrane from the skin with a shallow incision, which renders the operation less painful. Then, after the ligatures have been tied, I cut away the fold of mucous membrane so that it is quite unnecessary to plug the rectum.

<sup>1</sup> Goodsall and Miles: Diseases of the Anus and Rectum. Part II, page 11.

Illustrates how needles are passed through fold of mucous membrane, and dotted lines with arrow-points indicate the loops to be tied together. Three needles threaded on linen suture, three feet long. Small illustration shows suture tied and prolapse retracted.

The patient should be in the right lateral semi-prone position, with an assistant to support the left buttock, or in the lithotomy position. Personally, I have accustomed myself to operate with patients in the former position, and I think it is easier for them, both physically and mentally. A certain method of producing local anesthesia has been recommended for this operation, viz., blocking the pudic nerve trunk at its point of entrance into the ischio-rectal fossae. The lower rectum is enervated chiefly from the sacral plexus. Most of the nerves distributed here, such as the inferior hemorrhoidal, perineal and cutaneous are branches given off by the pudic nerve after it has entered the ischio-rectal fossae. This often proves unsuccessful, doubtless due to the fact that this region is still further supplied by certain nerves which come down through the inguinal canal, as well as others which originate independently in the coccygeal plexus. Therefore, to produce the

necessary anesthesia I infiltrate the structures all around the anus to a level well above the internal sphincter. This requires from two to four ounces of 0.5% novocain. (Novocain grs. 8, adrenalin gtts. 10, normal saline solution  $\bar{v}$ iv freshly prepared and sterilized by boiling.) The principles of this method were first described by Reclus, and have since been further elaborated by Brann. Caution should be exercised not to infiltrate within the muscular wall of the rectum, as this produces an edema of the mucosa, which renders it difficult to estimate how much should be removed at operation. If one's technique has been good the anesthesia does not involve any more discomfort than the first prick of the needle.

Anesthesia now having been accomplished, the mass, if not already protruded, is brought down by digital manipulation. The prolapsed fold of the right side is now slightly elevated, with a couple of hemostats and an incision made

with scissors at the muco-cutaneous juncture about a quarter of an inch deep. While making moderate traction in a downward direction, the three curved needles, which have been previously threaded on a linen ligature a yard long, are passed in at the line of incision and brought out at the upper part of the prolapse in the following manner. The middle needle is first passed in the centre, and the other two needles are inserted on either side of the middle one, thus dividing the fold into four equal portions. The four loops are now identified, the needles cut off, and each loop in turn tied very tightly. In this way the entire fold is completely strangulated, and as the ligatures are not interlocked, there is no occlusion of the anal canal. The operation is completed by excising a goodly portion of the mucous membrane below the ligatures, care being taken to leave enough so that they will not slip off. When the prolapse is bilateral the same procedure is carried out on the other side. It not infrequently happens that the fold on one side is much smaller than the other. In such instances one, two or three loops and, therefore, fewer needles, according to the size of the prolapse, will be found sufficient.

The bowels are moved on the second day after operation and daily thereafter with some mild aperient or cathartic. The anal region should be carefully cleansed three times daily by an experienced nurse and protected from external infection by a fluffy pad of sterile gauze. The average patient may expect to resume the activities of his normal life in a week or ten days.

Advantages of the operation.

1. It can be painlessly performed under local anesthesia, an important consideration in some of these aged debilitated patients. 2. Short operation. 3. Absence of hemorrhage. 4. The end-results are always satisfactory, and a recurrence is practically impossible. (5) This method of applying the ligatures brings about a more normal repair than any other operation. In fact, it is often impossible, after an interval of three or four months, to determine whether any operation has been performed.

#### ECONOMIC LOSS FROM TYPHOID AND MALARIA.

—In a recent address on rural health at Washington, D. C., on July 14, Senator Ransdall of Louisiana, chairman of the Senate committee on public health, estimated the annual economic loss in the United States from typhoid fever to be \$271,932,880, and that from malaria, \$694,904,750, a total of \$928,234,880, representing a per capita loss of \$9.46 from these two diseases. These figures are impressive and doubtless are, in a sense, a measure of the preventable evil of these diseases. It is to be remembered, however, that they are open to criticism on the basis of the economic fallacies to which all such hypothetical estimates are liable.

## SCIENTIFIC RESEARCH IN CHRONIC MEDICINE FROM THE PHYSIOLOGICAL POINT OF VIEW.\*

THE WORK OF THE ROBERT B. BRIGHAM HOSPITAL.

BY FRANCIS H. MCCRUDDEN, M.D., S.R., BOSTON.

*Laboratory Director, Robert B. Brigham Hospital, Boston; Assistant Professor of Applied Therapeutics, Tufts Medical School.*

MANY persons imagine that a sharp distinction can be drawn between treatment on the one hand and research on the other; that the one is intended to help the patient, the other to satisfy the idle curiosity of the doctor concerning abstract scientific problems remote from the practical needs of the individual patient. This feeling is entirely unjustified; the term scientific search implies certain intellectual methods rather than problems of any particular nature; and such methods are as applicable to the study of conditions in an individual patient as to the more abstract problems of physiology. The nature of the problems selected for study, and the direction in which clues are followed up depend on the personal interests, opportunities, and point of view of the scientific worker.

I can best bring out the significance of these statements by giving, as a concrete example of what the physiological point of view\* implies in the way of research, a brief account of some of the work of the Robert B. Brigham Hospital—a hospital for chronic disease, all of whose activities are based on the striking foundation that the treatment of chronic disease is a problem of applied physiology, and that chronic disease can be successfully treated.

When this hospital† opened its doors about a year and a half ago, two widely different courses were open to those responsible for its character; they might have adopted the hopeless anatomical view of disease and founded a home in which decrepit men and women could receive shelter and food, and pass their declining days in peace—a dreary congeries of helpless and hopeless misery, with death as its goal; or they might have taken the stand that provision of this kind was already abundant, and that the broad point of view expressed in the will gave them a glorious opportunity to found a hospital for chronic disease where the outlook given by the physiological view of disease, not helplessness and hopelessness, but help and hope, were to be the guides, and an efficient life the goal. The decision that the broad, hopeful attitude should be taken, gave

\* Address before the Interurban Orthopedic Club, December 31, 1915.

† See F. H. McCrudden: The Treatment of Chronic Disease Is a Problem of Applied Physiology, *Boston Med. and Surg. Jour.*, July 12, 1916.

‡ Embodied under the will of Robert and Elizabeth Brigham "for the care and support, and medical and surgical treatment, of those citizens of Boston who are without the necessary means of support, and are incapable of obtaining a comfortable livelihood by reason of chronic or incurable disease or permanent physical disability."

the community, for the first time, the benefit of a hospital where this hopeful physiological aspect of the purpose and principles of therapeutics in chronic disease is definitely emphasized.

The direction thereby given to our activities by the recognition of this great truth is shown in many ways. In the organization of the medical staff, for example, we do not have several different services—medical, surgical, orthopedic, etc.—to which patients are admitted for special treatment according to the exact anatomical nature and distribution of the lesion; but we have only one service or department; and treatment is directed at improving the functional efficiency of the patient as a whole. We have the various specialists on the staff; but an individual does not come into the hospital as an "orthopedic case," for example; he comes in as a "patient." It has been interesting to observe how the point of view is reflected, too, in the attitude of the patients; there is a distinct atmosphere of cheerfulness, hopefulness, and ambition to improve. These and other details relating to organization and administration lie outside my province; and I allude to them only to bring out the fact that the character of the scientific research—my part of the work—is but one of several phases of the work, all of which reflect our hopeful physiological point of view.

In such a hospital it is impossible to restrict ourselves to methods of treatment which have been discovered and proved out elsewhere; we must, ourselves, carry on research with the view of initiating improvement. For this purpose all necessary material facilities were afforded from the very beginning; more than this, the research work was encouraged to develop entirely free from the unnecessary restrictions and handicaps that so often discourage, hinder, and even entirely prevent such work in many institutions.

The point of view regarding purpose and principles of treatment which characterizes our hospital committed us to certain lines of research; and any tendency toward getting out of touch with problems of practical therapeutic interest—a tendency sometimes found in the case of the detached laboratory worker—has been entirely averted in our laboratory by the constant stimulus coming to us from the daily observation of patients under treatment; since the purpose of treatment in chronic disease is improvement in function rather than restoration of the anatomical integrity of diseased organs, it is clear that the research should be mainly in the field of physiology and chemistry—sciences which deal with function—rather than in the less hopeful field of anatomical pathology.

The field of scientific activities thus outlined has very wide and elastic limits; we are not restricted to any one kind of work; but our point of view does give definite form to the ideas which guide us in selecting problems, and in determining in what direction to follow clues. The problems are somewhat different from those of acute medicine, where the most important prac-

tical objects of research relate to the development of exact methods of diagnosis, the discovery of direct, specific methods of treatment, and the development and establishment of schemes of preventive medicine. One of the most important objects of research in chronic medicine concerns itself with the development of methods for a more exact measurement of functional efficiency. The details of treatment in chronic medicine depend very much on the *severity* of the disease, on the *degree* to which functional efficiency is impaired. Since scarcely a beginning has been made in methods for the exact measurement of functional efficiency, estimates of the severity of impairment of function, and of the degree of change, whether for better or worse, in the severity of the disease under any form of treatment, depend on the judgment of the physician. Judgment concerning the degree of disturbance of a function like that of the circulation, depends on estimates of the severity of the dyspnea, cyanosis, weakness on exertion, and other more subtle changes; these changes cannot be very exactly measured; estimation of their severity is subject to errors of judgment on the part of both the patient and the physician; some of them, too, may be only secondary changes and not directly proportional to the severity of the disease. Contrast with this, the situation in diabetes, a situation which is the direct result of research in biological chemistry; the severity of the disease in any particular case of diabetes is proportional to the amount of sugar which the body can oxidize; and since this can be accurately measured and stated in figures, the effectiveness of the treatment, the direction in which it is leading the patient, can be quickly, accurately, and objectively measured by determining how these figures change as the result of the treatment. The advances that have been made in the treatment of diabetes have depended entirely on our ability to measure the influence of treatment on the severity of the diabetes in this immediate, accurate, and objective manner. Innumerable other examples might be cited; in many of the more complicated cases, the direct relationship of the research problems to treatment is not so clear at first sight to one who does not understand all the factors involved. These considerations show how impossible it is to draw any line between what is simply treatment and what is scientific research; and they make clear the importance of developing methods of quickly and accurately estimating the results of treatment to replace or supplement the less exact guesses of the clinician.

The following are a few examples of investigations of this character which we already have under way. A method has recently become available for accurately determining the amount of uric acid in small quantities of blood, thus giving an opportunity for investigating the truth of the alleged relationship between uric acid and gout; we are trying to determine whether the uric acid content of the blood is high in gout; whether the

amount in the blood or the amount excreted is influenced by the attack; whether treatment—atophan treatment, radium treatment, for example—can influence these factors; and whether such treatment has any influence on the clinical condition; and, finally, whether the different clinical forms of the chronic arthropathies show any differences with respect to uric acid metabolism. The investigation has been extended to compounds other than uric acid; and we have some evidence that the creatinin metabolism may possibly be of even more importance than that of uric acid. In our studies of certain types of pernicious anemia we have become convinced that a determination, with the aid of the spectroscope, of the amount of urobilin formed from the destroyed blood pigment and excreted, gives a more correct picture of the functional condition, the direction in which the disease is going, the severity of the disease, than the simple "snap-shots" of the status given at any one time by counts of the number of red cells and determination of the amount of hemoglobin in the blood. Investigations of the sugar content of the blood which we have under way, suggest that a decrease in the amount of blood sugar may, possibly, be of as much significance in certain conditions of muscular asthenia as an increase in blood sugar is in diabetes; the finding of a low blood sugar content in progressive muscular dystrophy suggested the use of therapeutic measures to increase the blood sugar content; such measures were followed by prompt improvement in the clinical condition. Investigations which we have been carrying out on the relation of the calcium metabolism to certain bone diseases belong also in this category. The findings in all these cases may well have a direct bearing on the etiology of the diseases in question; but ultimate etiology, like all other ultimate cause, has a way of receding as the investigator advances—the symptoms of diabetes, for example, were first found to be due to loss of sugar through the kidneys; this, in turn, being found due to high blood sugar; the high blood sugar to inability of the body to utilize sugar properly; the inability of the body to utilize sugar, to the absence of a certain enzyme; the absence of the enzyme to disease of the pancreas; discovery of the cause of the pancreatic disease will push the question of etiology one step further.\* Expressed from our point of view, the findings are more significant; they are concrete examples of research intended to advance therapeutics by affording a more precise estimation of the severity of the disease, and of the effect of treatment on the severity.

Two other classes of problems peculiar to chronic medicine relate, respectively, to preventive treatment, and to the possibility of radical cure in chronic disease. The problem of *preventive treatment* is one of a different nature from that of preventive medicine in acute disease; it deals with the intrinsic rather than the extrinsic

factors responsible for disease. What is to be done with persons showing congenital or acquired tendencies to different chronic diseases? Until two generations ago, it was believed that people could be classified into different types—phlegmatic, nervous, bilious, etc., and that each type has a special liability to certain definite diseases; the demonstration that infection with micro-organisms is the cause of a large proportion of acute disease; and that such infection seems to depend more on accident than on any inborn tendency, led to a shifting of the emphasis from the "soil to the seed." In recent years a further readjustment of emphasis, especially in the case of chronic disease, is bringing the question of "type," of diathesis, of the "soil" as contrasted with the "seed," again into prominence; and our physiological point of view has led us to make the facts, pointed out by the pathological anatomists, factors to be used as the basis of treatment. As an example of the kind of problem dealing with the possibility of *radical cure*: gall stones of a certain type—those composed of cholesterin—have been hitherto, even with the aid of Roentgenographic examination, often unrecognizable, and, consequently, often the cause of serious chronic disease; research carried on at the Robert B. Brigham Hospital has made it possible, in certain cases, to recognize cholesterin gall stones, so that they can be removed by surgical operation.

The problems mentioned so far are all problems peculiar to chronic medicine and problems which we have attacked with premeditated deliberation; chance, the good fortune to have suitable patients to study, has played, of course, a part in the work; but those problems were not brought to our attention by the chance occurrence of suitable cases to study; we were searching for proper patients. Another kind of problem is that coming to our attention by the chance occurrence of a case suitable for some special study, a classical example of which is familiar to everyone in the studies of gastric digestion made on the hunter Alexis St. Martin who, as the result of an accidental gunshot wound, had a permanent opening through the abdominal wall into the stomach, an opening which enabled Dr. Beaumont to study the phenomena of gastric digestion. In our hospital the long stay of patients, the excellent laboratory facilities, and the close relationship between laboratory worker and patient make this an especially fertile field. One example: in the case of a young woman upon whom colostomy had been performed, the contents of the small intestine were evacuated through the right side of the abdomen and did not pass into the large intestine; we were able to study digestion, absorption, and bacterial activity in the large and small intestine separately; and to investigate the question of the digestion and absorption of enomata in the large bowel without the usual complications resulting from the carrying down of digestive enzymes

\* Every solution of a problem is a new problem—Goethe.

from the small intestine, and to the carrying backward of the enemata into the small intestine as a result of antiperistalsis.

Studies of another kind: much valuable pathological-anatomical information is derived in most hospitals from the results of post-mortem examinations; in this hospital, the emphasis laid on physiological chemistry makes possible an extension of this kind of information so as to include chemical examination of specimens seen post-mortem. I will refer only to the data already obtained by chemical examination of bones in pathological conditions, calcified tumors, sclerosed arteries, and other pathological lime-containing material, a subject in which we are especially interested here.

Besides such problems directly attacking the border line of the known and unknown, we have had problems relating to the practical application in therapeutics of new fundamental scientific knowledge: I will refer to but one example: the application in the dietetic treatment of disease of some of the recent advances in the physiological chemistry of nutrition. The enormous amount of valuable data concerning nutrition accumulated in recent years has led to the training of dietitians and their installation in many hospitals; but even a slight acquaintance with the literature on the subject will show much criticism and great disappointment in the practical results, a disappointment that can be attributed chiefly to the failure on the part of the physician, due to lack of acquaintance with the subject, to recognize the bearing of dietetics on treatment, and make intelligent use of the facilities thus offered him. The results at this hospital have been surprisingly successful.

A problem of a still different nature relates to the mechanism and methods of actually carrying out careful and accurate scientific work in a busy hospital; of how to check and control the work—metabolism observations, for example—so as to avoid errors. In the greater part of the metabolism observations reported in the literature, nothing but the belief of the investigator is usually obtainable that the work—such an important factor even as the completeness of collection of 24-hour specimens of urine—has been carried on with accuracy and care; but even with the most reliable assistance, and with the most perfect system, such belief is of little value if not backed up by objective evidence in the form of constant creatinin excretion from day to day. In our attempts to overcome the difficulties of this problem there have been times when the question has been, not, "How to do it," but, "Can it be done?" Though to the practicing physician problems of this kind may appear abstract in their nature, remote from practical therapeutics, and therefore, the least interesting and important of the investigations, they are, as a matter of fact, very important; the correctness of the conclusions regarding any methods of treatment or the results of treatment based on

laboratory findings depends on the reliability of the results; as an absolutely indispensable part of any investigation whose ultimate purpose is the advancement of therapeutics there are usually associated these tedious and time-consuming preliminary and accessory investigations whose purpose is that of establishing the integrity of the final results; like the scaffolding and the organization necessary for the construction of a building, though they do not appear in the final results, they were indispensable in its preparation. This problem has certain very important aspects that are often difficult of solution, and for which no generally applicable formula can be given; namely, those aspects relating, not to the purely scientific part of the problem, but to personal relationships, discipline, coöperation: in order to obtain reliable results it is necessary to have all the conditions under perfect control, and this necessitates a very rigid discipline in the carrying out of the work; it is necessary, on the other hand, to have the hearty coöperation of patients, nurses, and others taking part in the investigations, and this implies, what seems at first sight the opposite condition, namely, great individual freedom. This is a big subject, a discussion of which would be out of place here; but I feel confident in saying that our success in this direction is probably unequalled elsewhere.

It is impossible to give here more than a faint adumbration of the scientific work of the Robert B. Brigham Hospital; but this is sufficient to bring out an important point; namely that it is our recognition of the physiological aspect of the problem of treatment that has determined the nature of the scientific problems selected for study, and the success which we have had in attacking them. This is significant, for it justly entitles us to credit for originality in the recognition of a great truth. The facts upon which we have based our point of view have been known before; and individual physicians have adopted this point of view with respect to certain patients and even certain chronic diseases; but the bearing of the facts on the treatment of chronic disease in general has not, heretofore, been recognized to the extent of founding an institution with this point of view as the basis for all its activities.

This fact is a vital point in determining priority in the recognition of the truth. Priority concerning the discovery and publication of a fact—often enough, indeed, the subject of dispute—can, nevertheless, usually be determined with some degree of certainty; but a determination of the originality of a truth, a point of view, is much more difficult. If the facts upon which the point of view is based have been known, and some parts of the truth have been previously recognized, it requires no great dialectical subtlety to show, by so emphasizing these known and recognized elements, that the

whole point of view is merely a restatement of old knowledge; the important thing, however, is not the elements that go to make up the truth, but the way in which these elements are selected, arranged, and emphasized; this is a matter of synthesis; and judgment regarding the potency, vitality, and originality of the point of view so developed must rest, *not on an analysis of the point of view into its original dead elements, but upon the effect resultant from adopting the point of view.* Every restatement of the facts with a new arrangement and new distribution of emphasis does not establish a new truth: the deciding factor must be whether the truth as stated is a distinct entity that has, as such, a force for stimulating and directing the activities to accomplish something new; such a truth is a live and vital thing; and its power and originality must be judged by the character and extent of these stimulating, guiding, and illuminating effects. This hospital is the first hospital where the physiological point of view regarding the purpose and principles of treating chronic disease has served to guide, direct, stimulate, and illuminate all the activities and problems of the hospital.

If the brilliant medical period of the last half century may be called the "pathological-anatomical-bacteriological," the coming period, the one foreshadowed by the activities of the newer physiological chemical investigators, may be called the "functional," or "physiological-chemical" period. *And since the Robert B. Brigham Hospital gives definite recognition to this view for the first time, it is my conviction that the inauguration of the work of this hospital is one of the most important events in recent medical history.*

### Clinical Department.

#### EPIDURAL INTRASPINAL TUMOR OF TWO YEARS' DURATION; OPERATION; RECOVERY.

By W. E. PAUL, M.D., BOSTON.

(From the Neurological Department of the Massachusetts General Hospital.)

In a recent paper, Dr. Collins and Dr. Marks, commenting on cord tumors,\* state: "Pain and other classical data are valuable but not essential phenomena.... We urge that the term atypical be discarded from the symptomatology of cord tumors. Painlessly advancing tumors are not atypical. They form a definite and important group more significant because less tangible than the classical series." The following case seems to corroborate their opinion.

\* Am. Jour. of the Med. Sciences, January 15, No. 1, Vol. clix, p. 103.

N. T. L., a rugged woman, 43 years old, single, first noticed in November, 1913, that her feet were clumsy in walking. One night she had a backache and after it found her legs more clumsy. Soon some numbness gradually developed in her feet, and she stumbled and fell down at times; it was difficult to step up to the curbstone. Hot water was not felt by the left foot and the numbness began to increase upward in the left leg so that she did not feel the prick of a pin in it. The right leg was weak, but a pin prick and heat were recognized. There was no pain or tenderness and the sphincters were unimpaired. Some eight weeks elapsed during which the foregoing symptoms developed. On Dr. Putnam's advice, she then entered the Massachusetts General Hospital, in January, 1914. Examination showed the pupils equal and they reacted well to light and distance; the knee jerks were lively, especially the right; the position sense in the toes was normal; the ankle jerks were present; Babinski was suggested on the right but there was no clonus; the abdominal reflexes were not obtained; touch was felt everywhere without apparent loss; the temperature and pain senses were diminished throughout the left leg and left half of the trunk to a level just above the umbilicus; on the right there was also impairment of pain and temperature appreciations. The gait was notably unsteady. Both the blood and spinal fluid were negative to the Wassermann test. The x-ray revealed nothing abnormal in the vertebrae. The case was deemed a syringomyelia.

In December, 1914, N. T. L. reentered the hospital with accentuation of her previous symptoms. The gait was more ataxic and she stumbled and fell frequently. A Babinski was present on the right. The touch sense was everywhere preserved but pain and temperature were appreciated very imperfectly up to the eighth dorsal level. She was again sent home as a case of syringomyelia.

August 3, 1915, she entered the hospital a third time and was hardly able to get about even by taking hold of chairs. She had a marked Romberg; a clonus had developed on the right and there was a double patella clonus; Babinski existed on the right only. Reinforcement brought out the Babinski and clonus.

Touch sense was preserved but pain and temperature senses were practically lost up to the sixth dorsal level. Hard pulling of the pubic hair was painless. The level of loss was somewhat higher on the left. Though touch was appreciated everywhere, the change of sensation at the sixth dorsal level was determined by the pin point as being different and less natural below this level than above it; it was not determined by sharp delimitation of pain and temperature sensibility at this level.

The spinal fluid showed as follows at the three different times she was house patient:

	Jan. 9, 1914.	December, 1914.	August, 1915
Pressure	150	(No record)	210
Cell count	8	1	5
Noguchi	3 plus	Strongly positive	Strongly positive
Gold	Pathologic	Syphilis	Syphilis
chloride	neg. for syphilis		or non-tuberculous
Alcohol	(No record)	Strongly positive	Moderately positive
Wassermann	Negative	Negative	Negative
Roemer	(No record)	Very faintly positive	Moderately positive

The objective symptoms pointed to intramedullary disease of the cord, and in the first eight weeks of the disease it was regarded as a myelitis. Later the evidence seemed to justify the view that syringomyelia existed.

At the last visit in August, 1915, the suspicion of a tumor other than gliosis was strengthened by the partial degree of spinal impairment combined with the marked level of sensory change at the sixth dorsal segment. Inasmuch as the future was hopeless if nothing were done, an exploratory laminectomy was advised. The third, fourth, fifth and sixth dorsal spines were removed and the fourth, fifth and sixth laminae, by Dr. W. J. Mixer, on August 17. A tumor presented at the fifth dorsal level protruding posteriorly and extending transversely. It was unattached except at the point of emergence of the fifth right dorsal root, and when cut free, the tumor was lifted off with the escape of considerable cerebrospinal fluid. The tumor was irregular, lobulated, 4 by 2 cm.; a cup-like depression existed in the fifth dorsal vertebra conforming to the tumor.

Dr. J. H. Wright's pathological report follows:

"An irregular spherical mass of tissue 3 cm. in greatest dimension. Microscopic examination of a paraffin section shows a tissue very rich in delicate fibrils among which are scattered rather small nuclei. The nuclei are frequently disposed in groups. The fibrils are frequently arranged in small bundles lying parallel to one another. Mallory's phosphotungstic acid haematoxylin fails to stain the fibrils blue. Fibrosarcoma."

Surgical recovery was uncomplicated and functional return was very rapid, so that at the end of eight weeks after removal of the neoplasm the use of the legs seemed practically normal and sensory restoration had taken place. The reflexes were still active but the Babinski and clonus had disappeared. I had told the patient I would be satisfied when she could hop on either foot, and she now executes a very creditable hop. Six months after the operation she states she is able to use her legs as well as ever she was.

It would be of interest to examine the progress of symptoms from cord pressure to determine whether any typical order existed. Are all the nerve tracts affected alike? Do they fail one after another with a certain order of functional block? In this case there was successive failure of tracts, and the order approximately was (1) posterior columns; (2) lateral tracts; (3) antero-lateral tracts; (4) sphincter-controlling tracts. Least vulnerable were the tracts conveying touch sense. The order of severity is practically the same as that for invasion. And in keeping with the right-sided location of the tumor is the partial Brown-Séquard distribution of symptoms suggested by the greater spasticity on the right and by the greater sensory impairment on the left.

The time development of symptoms as well perhaps as the absence of subjective pain indicates the effects of the pressure were chiefly on the columnar tracts and not on the roots or commissural crossings of the temperature and pain tracts.

## PATHOLOGY OF CLAVUS (SOFT CORN).

By HENRY M. CHASE, M.D., F.A.C.S., BOSTON.

OLD DEFINITION: Small, circumscribed, horny elevation appearing upon the feet. When bathed in perspiration, they become more or less macerated and in this condition constitute the so-called soft corn.

The writer herewith presents a series of observations which will modify our interpretation of a condition which by most people is thought to belong to the care of the chiropodist; by others, as too annoying or too humiliating to discuss; by others not of sufficient magnitude to justify a medical expense.

It is a condition patiently, and as far as possible secretly, borne by most people. It is reasonably a cause of painful feet, for the origin of which search has been made elsewhere. It is a permanently curable condition.

CASE 1. J. W. Pain and redness above little toe. Thickened, moist epithelium between fourth and fifth toes. Examination shows a small infected sinus opening on one side of thickened epithelial area. Cocaine. Careful dissection of tortuous channel as outlined in Fig I A. At the bottom of the channel the glistening surface of the tendon of the plantar flexor of the little toe could be seen moving in its sheath with motion of the toe.

Fig. I B shows channel after dissection of the thickened epithelium and excision of the sinus.

Fig. I C, final cicatricial healing by granulation. Operation Nov. 14, 1912, healed Nov. 25, 1912. Now three years and four months. No recurrence.

CASE 2. W. B. A. Consultation in September, 1913, for pain about and below the external malleolus and along the fourth and fifth metatarsals, slight pronation. Pain thought to be due to static conditions, and so treated.

Not seen again for a year.

History in September, 1914. Soft corn between fourth and fifth toes for a year, apparent infection the last few days. Mild lymphangitis.

Sept. 30, 1914. Cocaine. Excision of thickened epithelium. Opening of sinus followed to dilated sac as in Fig. II A, at one side of which glistening tendon could be seen. Dilated channel not excised, wiped with carbolic and alcohol, packed with gauze (Fig. II B) followed by moderate discomfort.

Oct. 16, 1914. Escape of large amount of clear fluid (? from tendon sheath) carbolyzed and packed again. Followed by moderate discomfort.

Dec. 10, 1914. Cocaine. Excision of funnel-shaped channel. No carbolic, no packing. Dry gauze between toes. Plantar splint, transverse strapping of foot. No discomfort. Healed rapidly. Now one year, three months. No recurrence.

CASE 3. R. M. A. Feb. 22, 1914. Watery secretion and tenderness between fourth and fifth toes for several months.

Cocaine. Thickened epithelial surface excised and narrow funnel-shaped canal leading to dilated area adjacent and adherent to, but not apparently opening into, the plantar flexor tendon sheath of the little toe. Fig III A.

Carbolized and packed. Gauze removed in 48 hours. Fig. III B.

Sac apparently not sufficiently cauterized. Wiped with iodine, strapped and kept clean. Healed March 22, 1914. Now two years. No recurrence.

CASE 4. S. A. March 15, 1915. For six years has had a soft corn between fourth and fifth toes—healing and opening. Thick macerated skin one-fourth inch in diameter on outer side of fourth toe on left foot. A depression in the centre as of opening from below. Fig. IV A.

Cocaine and adrenalin. Tourniquet.

Macerated area excised and funnel-shaped sinus isolated to tendon sheath. Funnel ligated with fine iodized silk close to the tendon sheath, and excised. Wound wiped with iodine. Dry dressing. Fig. IV B.

This case had a long duration. The tie exfoliated and the wound closed to a fistulous tract secreting lymph. It was cocaineized and wiped with carbolic or iodine four times as each new funnel appeared to form. It really needed to have the foot securely strapped and the toe held still. It then healed in a very few days. Now one year. No recurrence.

CASE 5. M. F. (Referred by Dr. O. G. Tinkham.) March 9, 1916. Soft corn between fourth and fifth toes for three and one-half years. History of mild infection, off and on. Recently, for three weeks, tender, with lymphangitis along dorsum of foot over fourth metatarsal.

Cocaine. Bleeding controlled with pressure of hand of my associate. Probe enters opening in macerated area and demonstrates a sinus just below the epithelium. Skin excised and tortuous channel followed as outlined in Fig. V.

Funnel dissected and excised, exposing the gliding tendon of the plantar flexor.

Wound drained with small wick because of the lymphangitis. Removed in 48 hours since there was no discomfort. Foot strapped and gauze changed between the toes. Healed March 30th, 1916.

#### CONCLUSIONS.

Clavus, or soft corn, presents, on the surface, an area of thickened epidermis, moistened and at times macerated by discharge of lymph through an opening in the thickened area. This,

opening leads through a direct or indirect tortuous channel into the subcutaneous areolar tissue.

This lymph channel may or may not connect with a tendon sheath. It varies in length, according to its tortuous direction, from one to one and one-fourth inches in depth.

In none of the cases has it been possible to probe the sinus until the thickened epidermal layer has been removed as shown by the sharp change in direction of the channel.

*Treatment.* Dissection and excision of the lymph sac. If wall tears and is too thin to excise, wipe with carbolic acid and insert small wick for 48 hours.

Transverse adhesive strapping the entire length of the metatarsals. Keep the toes still. Change gauze dressing as necessary, lymph secretion may be slight or excessive for several days.

Healing by granulation and permanent cure.

of esophagus and cardia. This was sutured with great difficulty. A gauze walling-off drain was inserted between liver and stomach. Another gauze below stomach and a large drain to the back of abdominal cavity.

He was put to bed in good condition.

For first week was given nothing by mouth but sips of water, and was fed with peptonized food by rectum.

Fifth or sixth day gauze removed and new wicks reinserted.

In a few days I thought there was some leakage of gas. The morning after operation the nurse reported large amount of blood in urine. I was never able to find any blood visible in urine afterwards. It is possible that the left kidney may have been wounded.

After first week patient fed by stomach. Purulent fluid was taken care of by the long drain and later by a tube.

Patient discharged with slight sinus April 29, 1916. Later in June I saw him in Court House in New Bedford in perfect health.

## PISTOL-SHOT WOUND OF THE STOMACH.

By CHARLES A. ATWOOD, M.D., TAUNTON, MASS.

*Surgeon to Morton Hospital.*

MARCH 9, 1916. T. G., 35 years of age, single, Italian, employed at Mount Hope Finishing Company, and residing at Taunton, got into an altercation with another Italian, A. A., who demanded that G. give up his money. This, G. refused, and A. proceeded to empty a 38-calibre revolver at G., while the latter was running away. One bullet took effect in G.'s back. G. ran several hundred yards, to the railroad station, where he fell in a collapsed condition.

He was taken to Morton Hospital, where I saw him a short time after the accident. General condition good. There is a bullet wound of entrance in left back, apparently just above left kidney region. Abdomen rigid. The bullet can be felt in the anterior abdominal wall midway between the xiphoid cartilage and the umbilicus.

The patient was immediately prepared on the table for laparotomy.

Incision made through right rectus, bullet removed and abdominal cavity opened.

The anterior wall of stomach shows wound of exit of bullet. There is also a wound (slight) of the liver. Field walled off with gauze. Wound in liver packed. Anterior wound of stomach closed with interrupted chromic gut stitches, then infolded and sewed over by Lambert continuous suture. Opening made into cavity of great omentum between stomach and transverse colon. Stomach turned up.

I was at a loss to find posterior opening, and there was a leakage of stomach contents, with the odor of sour beer in considerable quantity. The posterior opening was found high up, at junction

## Book Reviews.

*The Umbilicus and Its Diseases.* By THOMAS STEPHEN CULLEN, Associate Professor of Gynecology in the Johns Hopkins University, Assistant Visiting Gynecologist to the Johns Hopkins Hospital. Illustrated by MAX BRÜDEL. Philadelphia and London: W. B. Saunders Company, 1916.

This monograph deals with the embryology, anatomy, and diseases of the umbilicus, together with those of the urachus. It should hardly seem, at casual thought, that there would be enough material on this subject for more than a brief treatise, yet the author has produced a large quarto of 680 pages. It constitutes a really complete survey of the literature upon the umbilicus and urachus, with the exception of umbilical hernia, and this survey is enriched with a large amount of original observation. Three-quarters of the volume are devoted to the umbilicus, one-fourth to the urachus, and the whole profusely illustrated with 269 text-figures and 7 plates, many of them original and some colored. The work is one of the best Teutonic type of thoroughness and value, written by an American in a charming and delightful English literary style unusual among physicians.

## THE BOSTON

**Medical and Surgical Journal**

Established in 1812

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

**SUBSCRIPTION TERMS:** \$5.00 per year, in advance, postage paid, for the United States. \$6.50 per year for all foreign countries belonging to the Postal Union.

An editor will be in the editorial office daily, except Sunday, from twelve to one-thirty p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager.*

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

## PREVALENCE OF POLIOMYELITIS.

DURING the past week the prevalence of poliomyelitis has diminished in New York and increased in Massachusetts. On July 22 the number of cases in New York reached a total of 2662, with 558 deaths; and in New York State, outside of New York City, 195 cases and 16 deaths had been reported.

In Massachusetts on July 23 the total number of cases since July 1 was 71, of which 8 were in Westfield, 6 in New Bedford, 5 each in North Adams and Worcester, 3 each in Fall River and Dudley, 2 each in Lowell, Lawrence, Pittsfield, Newton and Medway, and 1 each in Maynard, Marlboro, Sheffield, Greenfield, Hawley, Holyoke, Norwood, Haverhill, Boston, Greenfield, West Hanover, Raynham, Malden, Palmer, Natick, Dartmouth and Springfield.

Elsewhere in New England other new cases have been reported as follows: At Pawtucket, R. I., 4 new cases and no deaths; at Valley

Falls, R. I., 1 case; at New Haven and at Bridgeport, Conn., 1 death each, and 1 new case at New Haven. The total number of cases now in Rhode Island is 22, and in Connecticut 59. Many of the New England cases are contacts from New York. Elsewhere in the United States the disease is chiefly prevalent in Illinois, where, on July 11, there was a total of 27 cases, and in New Jersey, where the total of reported cases on July 22 was 239.

In New York City extensive measures are being taken to combat the epidemic.

A conference was held at the Department of Health on July 6 to discuss, particularly, lines of investigation to be pursued during the present epidemic in order to learn more about the spread of the disease. Those present were Commissioner Emerson, Dr. William H. Park, Director of the Department's Laboratories, Dr. Louis C. Ager, Dr. George Draper of the Rockefeller Institute, Dr. Abraham Sophian, Dr. S. Josephine Baker, Director of the Department's Bureau of Child Hygiene, Dr. Josephine B. Neal and Dr. Charles Bolduan.

Commissioner Emerson reported to the Committee that he had met the Hon. William G. McAdoo, Secretary of the Treasury, at a conference at the Mayor's office, and that Secretary McAdoo had offered the services of the United States Public Health Service to the city to help stamp out the epidemic. The offer was gladly accepted and the Committee decided that the United States Public Health Service should be requested to take up especially the very difficult "carrier" problem, and should make both field epidemiological studies and laboratory studies with animal inoculations. According to the Committee, there was plenty of work in this field for at least six skilled investigators.

The laboratory investigations are very much hampered by the lack of monkeys. The Rockefeller Institute reports having over one hundred monkeys ready for shipment from the Philippine Islands, but that at present there is an embargo due to the presence on the Islands of certain animal diseases. The Committee requested Commissioner Emerson to enlist the aid of the United States Public Health Service to pass these shipments.

A letter will be sent to all large hospitals having well-equipped pathological departments, asking them to send material from fatal cases to the Health Department for examination and research study.

In pursuance of the offer of the United States Public Health Service, Secretary McAdoo, on July 11, requested from Congress an appropriation of \$135,000, to finance the work in New York. This appropriation was granted, and in addition the following resolution was adopted:

*Resolved*, That until Nov. 1, 1916, the Secretary of Labor be and he is hereby authorized in his discretion to utilize the available hospital facilities at the immigration station at Ellis Island, New York Harbor, for the purpose of housing and caring for indisposed persons from the city of New York and vicinity, under such conditions as the secretary of labor may prescribe, and without any expense to the United States Government; and all expenses for the maintenance of such buildings and damages sustained, as the result of the use thereof, shall be borne by the City or State of New York, or both."

On July 10, at Washington, D. C., a meeting was held of the general board of the Public Health Service, consisting of Surgeon-General Blue and Assistant Surgeons-General Glennan, Simpson, and Rucker. The first step taken as a result of the action of this conference was to order all railway and trolley cars entering or leaving New York City to be thoroughly cleaned and disinfected. To prevent the interstate spread of the disease will be the first aim of the work, and the second will be to undertake the scientific research into the problem of carriers and of the transmission of the disease. The United States Public Health Service has detailed the following officers to take charge of the work in New York: Dr. William C. Rucker, Dr. J. B. Stoner, Dr. Francis Edward, Dr. J. R. Riddon, Dr. J. R. Leake, Dr. C. W. Chaplin, Dr. J. G. Wilson, Dr. R. H. Heterick, Dr. Louis Schwartz, Dr. L. L. Williams, Jr., and Dr. T. A. Hughes.

On July 15 it was announced that the Rockefeller Foundation has appropriated the sum of \$50,000 as a contribution to finance the cost of combating the disease. With this money the New York Health Department has opened a new bureau, under direction of Dr. Alvah H. Doty to trace contacts and maintain a complete registry of cases.

---

#### TESTS FOR AIRMEN.

With the conquest of a new element, there has come a new set of medical problems arising from the action of an unfamiliar medium on the human organism. Besides the actual phys-

ical effects of alteration in the air pressure and rarefaction of the atmosphere, there are psychological effects which have been found to incapacitate many a would-be aviator. Airmen must, in fact, be picked men, especially if they are to be called upon for military duty, where, in addition to their ordinary functions, they must add those of attack and defense.

Realizing this, the French have devised a method of examination for applicants for the position of aviator, which, in addition to the ordinary physical examination which is given all recruits, comprises certain psychological tests. It is essential that the candidate's sense perceptions be in good order, so his quickness of response to auditory, visual and tactile impression is tested. Even more important, however, is the question of the stability of his emotional mechanism. He must not be unduly excitable, apprehensive or nervous.

The methods of exposing these defects seem rather spectacular, although it is probable that time will make commonplaces of many of these tests. The well-known smoked drum of the physiological laboratory is so arranged as to record the cardiac rhythm, the respiratory rhythm, the vasomotor tone, and the occurrence of muscular tremor. The candidate is then tried with unexpected noises—revolvers are fired off near him, and other loud noises made in his vicinity. Magnesium powder is ignited without warning, and searchlights flashed in his eyes to test his reaction to unexpected visual stimuli. Cold cloths are then applied suddenly to exposed parts of his skin and needles thrust into him.

The ideal candidate shows such slight reaction to these tests that his tracings show little or no change. Some candidates will react somewhat at first, until the purpose of the test is explained to them; they are then able to control their emotions completely. Other candidates show such marked tremor and irregularities in their heart action that it is considered probable that they would not be capable of handling an aeroplane in the presence of hostile forces, and these men are weeded out. Of course it is probable that some candidates are thus rejected who would not waver in the presence of actual danger, but probably the decision in most cases is a just one; certainly it is a more scientific way of going about the thing than the forming of a judgment based merely on the impression which a candidate makes on the examiner.

## MORE REPORTS OF APRAXIA.

A RATHER detailed report of a case of bilateral motor apraxia by Drs. Smith and Holmes, published in the *British Medical Journal* for March 25, reminds us of the fact that accounts of this rare and interesting condition are all too infrequent. The term dates back to its use by Gogol in 1873, although the phenomenon had been described before, notably by Hughlings Jackson, Quaglino, and Fikelnberg. Recent studies have been made by Liepmann, Pick, von Monakow, d'Hollander, and Wilson. The best report which has been made in American medical literature is that of Glasecock in 1913.

Too often apraxia is accompanied by such general psychic loss that the symptoms are overlooked. Such cases are found in asylums, and spoken of as being very demented, greatly deteriorated, etc. If these cases were more thoroughly investigated our knowledge of the condition would be more definite, and it would add, of course, to our knowledge of the functions of the various parts of the cortex. At present we can only say that apraxia results from a diaschisis of the left frontal area from the right frontal area.

The patient of Drs. Smith and Holmes confused yawning and whistling, was unable to use knife and fork correctly, or to shuffle cards, unable to correct the faulty position of a book handed him, showed difficulty in performing acts connected with smoking, although he was an ardent smoker, was unable to make movements of brushing his teeth or of washing his hands. There were also some disturbances of visual orientation and localization, so that he failed to appreciate the relative distance of two objects from him, and became lost in going from one part of the ward to the other.

The most disabling injuries in war are those of the skull, and these are common in trench warfare, which seems to be the approved modern method of fighting with infantry. This is due partly to the fact that the head is the most exposed part of the body in the trenches and to the frequency of enfilading fire. The more the profession learns about head injuries and their sequelae, the better will it be prepared for the exigencies of war.

## MEDICAL NOTES.

**PREVALENCE OF MALARIA, MENINGITIS, SMALL-POX AND TYPHOID FEVER.**—The weekly report of the United States Public Health Service for July 7 states that during the month of May, 1916, there were reported in California 114 cases of malaria, 9 of cerebro-spinal meningitis, 7 of pellagra, 18 of smallpox and 121 of typhoid fever. During the same period there were 146 cases of smallpox in Iowa, and in Montana 80 cases of smallpox and 18 of typhoid.

**AWARD OF VICTORIA CROSS TO A PHYSICIAN.**—In the *London Gazette* of June 21 it is announced that the Victoria Cross has been awarded to Captain John Alexander Sinton, M.B., I.M.S., for most conspicuous bravery and devotion to duty. "Although shot through both arms and through the side, he refused to go to hospital, and remained, as long as daylight lasted, attending to his duties under very heavy fire. In three previous actions Captain Sinton displayed the utmost bravery."

**ROCKEFELLER YELLOW FEVER COMMISSION.**—On June 14 the yellow fever commission of the International Health Board of the Rockefeller Foundation, under command of General William C. Gorgas, U.S.A., sailed from New York to study sanitary conditions in the Panama Canal Zone and on the west coast of South America, particularly with reference to the prevalence of yellow fever. This commission, which consists of six members besides General Gorgas, landed, on July 12, at Lima, Peru, to investigate sanitary conditions at the Port of Iquitos.

**WEIR MITCHELL MEMORIAL.**—The new dispensary building of the Philadelphia Orthopedic Hospital and Infirmary for Nervous Diseases has been formally dedicated to the memory of Dr. S. Weir Mitchell, a founder of the institution and for many years chief of its hospital staff. Suitable tablets have been placed in the building, stating that it is dedicated to Dr. Mitchell's memory by his friends and patients. The dedicatory address on this occasion was delivered by Dr. William W. Keen.

**HONORARY DEGREE FOR A PHYSICIAN.**—At the recent convocation of the University of Chicago in celebration of its twenty-fifth anniversary, the honorary degree of ScD. was conferred on Dr. Otto K. O. Folin, Hamilton Kuhn Professor of Biological Chemistry in the Harvard Medical School.

**BRAZILIAN ACADEMY OF SCIENCES.**—At the May meeting of the National Academy of Sciences at Rio de Janeiro, Brazil, Dr. Tom A. Williams, of Washington, D. C., was elected corresponding member for the United States.

**VARIATIONS IN COST OF DRUGS.**—During the past month the prices of various drugs affected by the European War have continued to fluctuate with perhaps a general tendency to decline, owing, in certain instances, such as aspirin, to the change in seasonal demand. On June 10, 1916, crude opium sold at \$11.50 a pound, antipyrin at \$30.00 a pound, caffeine and phenolphthalein at \$20.00 a pound and santalin at \$38.00. Among the drugs which have shown the highest advance in price are antipyrin, 2700%; potassium bromide, 1150%; potassium acetate, 800%; cod liver oil, 700%; caffeine, 370%; Epsom salts, 250%; and quinine, 200%.

Report from New York on July 7 contains the following statement of market conditions of certain drug products on that date:

"Spot quotations for caffeine alkaloid were given yesterday as \$16.50 to \$17.50 per pound. Demand for quinine is gradually increasing, as larger quantities are required in Mexico for the troops. Sellers quote 70 and 72½ cents, the outside quotation being more general. A sharp decline is noted in oxalic acid, which has been lowered to 56 cents per pound following the larger production. Norwegian oxalic is nominal owing to scarcity. Salicylic acid was easy at \$2.90. Citric and tartaric were quiet and somewhat easier."

Further report from New York on July 19 notes a recent sudden decline in the market cost of bromides, quinine, and caffeine alkaloid.

#### EUROPEAN WAR NOTES.

**AMERICAN FIELD AMBULANCE.**—Report from Paris on July 14 states that the field section of the American Ambulance Hospital at Neuilly has been separated from the main organization and established as an independent unit with 150 cars under command of A. Piatt Andrew of Gloucester, Mass., and Stephen Gallatin of New York:

"Of the cars now in service, 125 are on the Verdun front. New cars are being fitted out and young men are coming from the United States to drive them, so that by the end of August, 200 cars will be in service, or five times as many as a year ago. The field ambulance will have a suburban villa, where the drivers can rest when on furlough from the front. The unit now has its own repair stations at Billancourt, close to Paris."

**SELECTION OF WOUNDED FOR TREATMENT.**—A recent quotation from a French scientific journal gives some interesting facts about the manner in which great numbers of wounded soldiers are cared for by the first aid hospitals. During a period of attack when the army surgeons are called upon to care for an overwhelming number of wounded in a short space of time, those

suffering from wounds in the legs are chosen first. Wounds in the body, experience has shown, are best attended to in the base hospitals and better results can be obtained if these cases are sent directly to those hospitals without preliminary operations by the stations at the front. Wounds of the arm, less likely to become seriously infected than the leg, are preferably sent to interior hospitals where every effort can be made to prevent the loss of the hand. While the ambulances of the medical department have proved adequate in every way, even for severe operations, it has been found desirable, for the psychological effect upon the patient, to perform such services beyond the firing lines and in the zones of comparative safety where the base hospitals are located.

**AUSTRO-GERMAN MEDICAL CONGRESS.**—The Austro-German Medical Congress, whose occurrence we noted in previous issues of the JOURNAL, was held at Warsaw from May 1 to 3, and summarized reports of it have now appeared in the German and English medical periodicals. The address of welcome was delivered by His Excellency General von Beseler, governor of Warsaw and chief of the German Army Medical Service. Professor von Schjerning then gave an account and interesting survey of the organization of the German medical service.

"There were, he said, more than 24,000 doctors in the service of the army, of whom 16,000 were actively employed at the front. Besides these, the Army Medical Service included 3000 doctors employed in Red Cross work, 400 surgeon-dentists, 1800 pharmacists, and 92,000 men in the sanitary and ambulance departments. These were assisted by 72,000 voluntary nurses, male and female, at the base hospitals, and 22,000 in the war zone. Thousands of motor-cars and vans were engaged in transporting the sick and wounded to the war hospitals, of which there were 238 in the whole country. There were also thousands of installations for the sterilization of water, for disinfection, and x-ray examinations; 26 large mobile steam laundries were kept busy day and night for the military hospitals alone; and there were 18 large disinfecting stations through which 100,000 men could be passed daily and their clothes dealt with. The central medical depot forwarded to the front daily wagon-loads of medical preparations and surgical appliances. Surgeon-General His, the President of the Congress, spoke of the successes hitherto attained in combating epidemics, asserting that 'in spite of typhus and dysentery, spotted fever and cholera, the efficiency of the troops has never been impaired.' Several scientific investigators had lost their lives during the war in combating these and other invisible enemies, amongst them Cornet Prowazek, Lüthje, Joehmann, Römer, and Tilp. New diseases had been discovered, to one of which the name of 'five-day fever' had been

given. Well-known diseases, such as typhoid and dysentery, appeared in modified form, owing to previous inoculation."

With regard to the incidence of Asiatic cholera, an extensive statement was made by Colonel S. A. Hoffmann.

"He stated that Galicia had suffered terribly from the disease, which had also made its appearance among the German troops on the Polish frontier. The sickness rate, however, even among troops who had in the height of summer traversed the cholera-stricken Galicia and the Rokitno marshes, did not exceed 0.5%, or a quarter of the rate prevalent in the Greek army. Owing to the success of the inoculation carried on among the armies in October, 1914, only 10.2% of those attacked died, whereas the ease mortality among the uninoculated troops reached the high figure of 50%. In August, 1914, cholera broke out in Warsaw, and by September it had already infected 12,000 soldiers in the Serbian army. Isolated cases had also been detected in Germany, but thanks to prophylactic measures, only 78 German civilians had contracted cholera up to January, 1916. He attributed this relative immunity of the civilian population to inoculation, which had been almost completed when, in November, 1914, the first cases of cholera appeared in the army and among Russian prisoners. He did not give the figures for the German army, but he admitted that when the Germans were advancing in the region of the Bug and the Rokitno marshes, the morbidity among the German troops was 0.52%. The mortality among those attacked by the disease, which was 50 to 35%, was reduced by inoculation to from 20 to 10%. By killing cultures at a temperature 3 to 5° C. lower than before, the resulting vaccine, even when administered twice, had been found in most cases not to provoke a troublesome reaction. Inoculation had to be repeated after half a year, as the immunity conferred did not last more than seven to nine months. In addition to inoculation, the campaign against cholera was carried out by strict hygiene, which included the prohibition of drinking unboiled water and a ceaseless war on flies. From the beginning of the war to Jan. 1, 1916, the morbidity from cholera represented only 0.065% of the average strength of the army in the field and only 0.005% of the army of occupation. He touched on the part played by carriers, and stated that in one prisoners' camp 5 out of 600 healthy men proved to be carriers. Another speaker, Dr. Schemensky, drew attention to the difference in mortality when patients were nursed in bed or on the ground: it was 30% among the former, 45% among the latter.

"Professor Kaup, representing the Austro-Hungarian army, said that after the soldiers had been inoculated the morbidity was only 1 to 5%; even when exposure to infection was great, the course of the disease was strikingly

mild, and the mortality was only 0 to 20%, whereas the mortality among the uninoculated was 40 to 60%. As the immunity conferred by inoculation lasted only three to four months, it was repeated after three months if the soldiers were exposed to infection. On these occasions a single injection of 2 c.cm. of vaccine was sufficient."

**WAR RELIEF FUNDS.**—On July 22 the totals of the principal New England relief funds for the European War reached the following amounts:

Belgian Fund .....	\$133,945.12
Allied Fund .....	125,532.00
French Wounded Fund .....	100,102.43
Army Hut Fund .....	73,351.60
British Imperial Fund .....	61,118.90
French Orphanage Fund .....	57,563.30
Armenian Fund .....	54,832.77
Polish Fund .....	54,832.77
Surgical Dressings Fund .....	39,433.87
Belgian Tobacco Fund .....	31,495.88
Facial Hospital Fund .....	23,135.51
Permanent Blind Fund .....	2,883.13

#### MEXICAN NOTES.

**AMERICAN RED CROSS.**—In connection with the mobilization of our troops on our southwestern border, the American Red Cross has undertaken to collect and distribute soldiers' gifts and other relief supplies, and the various express companies have cordially coöperated in this humanitarian work and will accept such shipments at *two-thirds* of the regular rate.

Supplies contributed should fall within the following approved list only:

Reading matter, games, comfort bags, pajamas, cotton socks (medium weight, large sizes), towels, pipes and smoking tobacco, cigarettes, electric fans (to hospitals), chewing gum, chocolate in tin boxes, hard candies, instantaneous coffee, evaporated cream, and canned fruits and other delicacies in tins.

Surgical dressings and hospital supplies will be acceptable if made according to directions in Red Cross Circular No. 115. (For copies of same, address Bureau of Supplies, American Red Cross, Washington, D.C.)

Depots for the collection and distribution of supplies have been established at various points as follows:

1. Red Cross Supply Depot, Bush Terminal No. 19, South Brooklyn, N. Y.
2. Red Cross Supply Depot, 219 East Second street, Cincinnati, Ohio.
3. Red Cross Supply Depot, Clearing, Argo District, Chicago, Ill.
4. Red Cross Supply Depot, c/o Montgomery, Ward & Co., Kansas City, Mo.
5. Red Cross Supply Depot, Denver, Colo.
6. Red Cross Supply Depot, c/o Mr. A. B. C. Dohrmann, San Francisco, Cal.

7. Red Cross Supply Depot, c/o Mayor W. H. Adamson, Douglas, Ariz.

8. Red Cross Supply Depot, 516 San Francisco street, El Paso, Texas.

9. Red Cross Supply Depot, Avenue E and Fourth Street, San Antonio, Texas.

Contributions should be *prepaid* to the appropriate depot, whence shipments will be forwarded, without further charge to the contributor, to the troops at the front.

Enquire of local express agent as to depot to which *your* supplies should be sent.

N. B. Supplies cannot be accepted which are intended to be forwarded separately to designated individuals. Those who wish to send packages to particular persons are advised to employ the parcel post or express service, such service being at *regular* rates. Supplies intended for designated companies or regiments may be accepted for forwarding with the understanding that if such delivery is found to be impracticable these supplies may be donated to other troops.

In connection with the appeal of the Chairman of the Central Committee, Mr. Taft, dated June 26, 1916, for funds for aid to our soldiers and sailors on or near the Mexican border, which appeal, it is to be regretted, has been poorly responded to, numerous letters showing splendid work done by two chapters in giving needed aid and comfort to soldiers en route to the border, and the special need of financial assistance in carrying on this good work have been received.

Press reports indicate that other Red Cross Chapters along the routes followed by the troop trains exerted themselves in like manner early and late to provide comforts and necessities for militiamen.

It is just such good, patriotic and humanitarian work as this that will cause the name of the American Red Cross to be revered by every recipient of the timely aid and comfort given by it, and it is sincerely hoped that these illustrative letters of good Red Cross work may be the means of causing such of our chapters and auxiliaries as have not had an opportunity to take part in such work, to contribute liberally toward its continuance by those chapters which are called upon to do it.

Contributions should be sent to the American Red Cross, Washington, D. C., with purposes for which they are intended plainly stated.

ARTHUR MURRAY,

*Major General, U. S. A., (Retired),  
Acting Chairman, Central Committee.*

**APPEAL FOR SURGICAL DRESSINGS.**—The Surgical Dressings Committee of the National Civics Federation, which has been sending extensive supplies of surgical dressings to the Allied powers in the European War, has recently issued the following appeal for funds to enable it to undertake the additional labor of

furnishing dressings for United States troops on the Mexican border:

"As a result of the sudden mobilization of the United States troops on the Mexican border, the Surgical Dressings Committee finds its field of work greatly enlarged, with constantly increasing demands upon its resources.

Further contributions are, therefore, urgently needed. Checks may be sent to the Surgical Dressings Committee, care of Old Colony Trust Company. Those wishing their subscriptions to be used exclusively for the United States troops will please mark them 'Home Relief.'

MRS. FREDERICK S. MEAD,

*Chairman,*

MRS. HENRY B. CHAPIN,

MRS. LIVINGSTON CUSHING,

MISS ROSE L. DEXTER,

MRS. RICHARD M. SALTONSTALL,

*Acting Members Executive Committee."*

**CIVILIAN NURSES NEEDED.**—On July 12 a call was issued from the United States War Department at Washington, D. C., for several hundred civilian nurses to join the Army Nurse Corps, to fill the six base hospitals which have been established on the Mexican border.

"There are at present approximately 3000 beds in the six hospitals. To attend these, medical regulations call for 45 nurses and one chief nurse to every 500 beds. This will necessitate the employment of 276 additional nurses.

"None but graduate nurses will be accepted by the department, and they will receive a compensation of \$50 a month and maintenance and laundry during their employment. All candidates must be graduates and certified practitioners, must have studied in a school connected with a hospital containing not less than 100 beds, and pass mental and physical examination. The nurses who qualify will become members of the regular corps during manoeuvres, and later will be carried on the reserve."

**MASSACHUSETTS FIELD HOSPITAL No. 2.**—In last week's issue of the JOURNAL we described the organization of the Second Massachusetts Field Hospital. On July 16 this hospital unit was mustered into Federal service as Field Hospital No. 51 of the United States Army, and will soon depart for the front. It is under command of Major (formerly Captain) Charles R. Morgan. Its other commissioned officers are Captain William M. Penny and Lieutenants Walter H. Young, Harold F. Parker and Robert F. Souther.

**RELIEF FUNDS.**—On July 22, the totals of the two principal relief funds for Massachusetts troops in Mexico, and their families, reached the following amounts:

Volunteer Aid Fund .....	\$71,847.44
Home Relief Fund .....	1,469.00

## BOSTON AND NEW ENGLAND.

**THE WEEK'S DEATH RATE IN BOSTON.**—During the week ending July 22, 1916, there were 189 deaths reported, with a rate of 12.96 per 1000 population, as compared with 198 and a rate of 13.79 for the corresponding week of last year. There were 37 deaths under 1 year, as compared with 30 last year, and 46 deaths over 60 years of age, against 54 last year.

During the week the number of cases of principal reportable diseases were: diphtheria, 47; scarlet fever, 15; measles, 136; whooping cough, 30; typhoid fever, 5; and pulmonary tuberculosis, 61.

Included in the above were the following cases of non-residents: diphtheria, 13; scarlet fever, 2, and tuberculosis, 3.

Total deaths from these diseases were: diphtheria, 1; measles, 1; typhoid fever, 1; tuberculosis, 14.

**ADAMS NERVINE ASYLUM.**—The thirty-ninth annual report of the managers of the Adams Nervine Asylum states that more patients were admitted in the past year than ever before. There were 259 men and women under treatment in that time. Of this number 11 were discharged as recovered, 117 relieved, and 72 not relieved. The amount received from patients was about 38% of the expenses. While more patients were admitted, the average stay was less than in former years. Those patients who seemed not suitable for treatment, or not suffering primarily from a nervous trouble, either went home or were recommended to some other hospital. More work than ever before was done in the men's department, and the sanatorium is making an effort to acquaint the medical profession of this State with the facilities here offered for men.

**CRUISE OF THE ANDROSCOGGIN.**—United States Coast Guard Cutter *Androscoggin* returned on July 11 to Port of Boston from her latest cruise on the Grand Banks as a hospital ship, having made the farthest north that she has ever sailed. Many cases of sickness and incidental trauma were treated aboard the *Androscoggin* during her voyage.

**HOSPITAL GIFT.**—Report from New London, Conn., states that on July 14 the Lawrence Hospital of that city received an unrestricted gift of \$25,000 from Mrs. Morton F. Plant. It is probable that it will be used either for a new building or for addition to the present one.

## Obituary.

## LOUIS AUGUSTUS WOODBURY, M.D.

DR. LOUIS AUGUSTUS WOODBURY, a descendant of John Woodbury, who came to America with the Massachusetts Colony in 1624, and a prominent practitioner of Groveland, Mass., died at his home in that town, July 18, 1916, at the age of 71 years. The son of Washington and Dolly Head (Jones) Woodbury, he was born in Salem, Oct. 1, 1844. His education was obtained in the public schools of Concord, N. H., and at the age of 18 he entered the Union Army as a member of D Company, 16th New Hampshire Volunteers, serving until the company was mustered out. Entering the Harvard Medical School, he was graduated with the class of 1871 and settled in Groveland, where he practised medicine for the rest of his life, retiring about five years ago. He became a Fellow of the Massachusetts Medical Society in 1873, his name being placed on the retired list in June of this year.

Dr. Woodbury was a member of the New Hampshire Association of Army Surgeons, the Harvard Medical Alumni Association, the Haverhill Medical Club, the New England Historic Genealogical Society, the Essex Institute, and the Society of the Sons of the American Revolution. He was a Knight Templar.

In 1869 he married Alice Chester Stanwood. She died in 1889, and he married, in 1890, Helen Ney Robinson. His widow survives him. His writings include "A Contribution to the Early History of Medicine in Haverhill," "Inscriptions from the Old Cemetery in Groveland," "Early Ministers of Bradford," and "An Historical Sketch of Bradford in the Revolution."

## Miscellany.

## COMMUNICABLE DISEASES.

The striking facts of the communicable disease situation for June, 1916, are the continued high mortality for measles and the low incidence of typhoid fever.

**Prevalence.**—The communicable diseases, prevalent in about the same amount as during June of last year, have continued to be above the five-year average for June. As was noted last month, this increase above the average for the five-year period is due to the unusual prevalence of measles.

## TOTAL CASES REPORTED.

	June, 1915.	June, 1916.	Average for 5 Years, 1910-1914.
Cases .....	7525	7500†	4880*
Case incidence per 100,000..	204	203	139
Deaths .....	457*	402*	— ‡

Measles continues to be the most important factor in the communicable disease reports. There is very little variation between the number of cases reported last year during June and this year.

## TOTAL CASES REPORTED.

	June, 1915.	June, 1916.	Average for 5 Years, 1910-1914.
Cases .....	4054	4186	2362
Case incidence per 100,000..	110	113	67.4
Deaths .....	18*	42*	25.8

The center of greatest prevalence of measles has shifted during the last month. There have been fewer cases reported from Springfield and Worcester, while there has been an increase in the cases from Lowell and Fitchburg.

During June the following cities and towns have exceeded their endemic index: (Endemic index signifies the average for five years of reported cases exclusive of epidemics. This index is applied to each city and town for each month for every communicable disease.)

	Endemic Index.	Current Month.
Middleboro .....	1	27
Belmont .....	2	26
Bridgewater .....	2	111
Chicopee .....	6	47
Dartmouth .....	1	18
Fitchburg .....	11	129
Gardner .....	2	107
Hardwick .....	0	30
Holyoke .....	15	117
Grafton .....	0	24
Mansfield .....	1	73
Middleboro .....	1	44
Lowell .....	83	345
Newton .....	67	101
Palmer .....	1	102
Rockland .....	0	71
Shirley .....	0	92
Springfield .....	37	154
Warren .....	0	35
Williamstown .....	2	43
Worcester .....	58	242
E. Longmeadow .....	0	24
Brockton .....	33	107

Scarlet Fever shows a marked decrease, both in comparison with last month and with June, 1915. It is somewhat lower than the five-year average for the month of June.

## TOTAL CASES REPORTED.

	June, 1915.	June, 1916.	Average for 5 Years, 1910-1914.
Cases .....	885	460	514
Case incidence per 100,000..	23.9	12.5	14.6
Deaths .....	18*	14*	16.1

\* Bulletin figures. † Figures not available. ‡ Approximately.

There was a sharp decline in the number of cases of scarlet fever reported during the month of June. In Peabody there were more than the average number of cases reported, and investigation of the district health officer shows that they were due to "missed cases." The local board of health made a house-to-house inspection and has the situation under close observation.

The following cities and towns have exceeded their scarlet-fever endemic index for the month of June:

	Endemic Index.	Current Month.
Norwood .....	2	7
Peabody .....	2	18
Mendon .....	0	7
No. Brookfield .....	0	4
Holyoke .....	8	24

Whooping Cough has shown a slight decrease in amount, as compared with June of last year:

## TOTAL CASES REPORTED.

	June, 1915.	June, 1916.	Average for 5 Years, 1910-1914.
Cases .....	608	537	216*
Case incidence per 100,000..	16.5	14.6	6.2
Deaths .....	29*	11*	16

This infection was distributed over the eastern part of the state, with practically no reported case coming from districts 7 and 8. The following cities and towns have exceeded their whooping cough endemic index:

	Endemic Index.	Current Month.
Barnstable .....	1	8
Braintree .....	3	15
Brockton .....	9	85
Cambridge .....	5	29
Clinton .....	0	15
Lexington .....	1	18
Winchester .....	1	17
Stoughton .....	0	9
Fall River .....	7	16

Diphtheria.—There were about the same number of cases reported during June, 1916, as there were during the same month, 1915. This is considerably above the average for the five-year period. It is also a slight increase over last month.

## TOTAL CASES REPORTED.

	June, 1915.	June, 1916.	Average for 5 Years, 1910-1914.
Cases .....	609	567	496*
Case incidence per 100,000..	16.5	16.2	14.1
Deaths .....	35*	26*	43

The reported cases are scattered all over the state. The only points of infection of importance are Salem, Lynn, Haverhill and Oxford.

The following cities and towns have exceeded their diphtheria endemic index for the month of June:

\* Bulletin figures.

	Endemic Index.	Current Month.
Somerset .....	0	6
Quincy .....	7	16
Wrentham .....	0	7
Salem .....	4	21
Lynn .....	12	21
Haverhill .....	5	19
Lawrence .....	4	14
Oxford .....	0	13
Fitchburg .....	4	12

**Tuberculosis.**—The number of cases reported to this department during June showed a decrease in number compared with the same month last year and with the five-year average for June. It would seem that, with the increased machinery that we have for the detection of this disease, we should be getting an increased number of reports:

## TOTAL CASES REPORTED.

	June, 1915.	June, 1916.	Average for 5 Years, 1910-1914.
Cases .....	709	628	647
Case incidence per 100,000..	19.2	17.1	18.3
Deaths .....	276*	246*	364.2

**Typhoid Fever.**—The low incidence of typhoid fever, noted in last month's report, continues. The number of cases reported during June is markedly lower than the same month last year and the average for the five-year period. Fall River is the only city or town that has reported above its average of this disease. Even here the increase is only a slight one:

## TOTAL CASES REPORTED.

	June, 1915.	June, 1916.	Average for 5 Years, 1910-1914.
Cases .....	103	69	129
Case incidence per 100,000..	2.8	1.9	3.7
Deaths .....	12*	5*	19.4

**Mortality.**—There were 402 deaths reported to this department during June. Of this number 246 were caused by pulmonary tuberculosis and 44 by other forms of tuberculosis. The most important other cause of death was measles, which claimed 42 persons. Diphtheria was responsible for 26 deaths while whooping cough accounted for 11. There were four deaths from pellagra, 6 from cerebrospinal meningitis, 2 from tetanus and 1 from anthrax. The 5 deaths from typhoid fever, with 69 reported cases, gives comparatively low rate.

## RARE DISEASES.

**Trachoma** was reported from Boston (3), Fitchburg (1) and Woburn (1).

**Cerebrospinal Meningitis** was reported from the following places: Boston (8), Worcester (1), Fall River (1), and Cambridge (1).

**Malaria** was reported from Wellesley (2), Boston (3), Worcester (1), Springfield (1), and Newton (4).

\* Bulletin figures.

**Pellagra** was reported from Peabody (1), Danvers (3), Boston (1), and Worcester (1).

**Septic Sore Throat** from Boston (3), and Fall River (1).

**Dog-bite** (reported to this department). (Those marked "+" the laboratory examination showed the brain of the dog to be positive for rabies and are being given the Pasteur treatment.)

Attleboro (1), Montague (1), Hudson (1), Lowell (1), Lawrence (3), and N. Attleboro (1).

**Actinomyces** was reported from Winchendon (1).

**Smallpox** was reported from Fitchburg (1).

**Bacillary Dysentery** was reported from Natick (1).

## EPIDEMICS.

The septic sore throat epidemic in Watertown subsided promptly and with the exclusion of the infected cow from the milk supply.

During the course of the month there have been five additional cases of anthrax reported to the department and distributed as follows:

Woburn (3), Winchester (1), Norwood (1). All of these individuals were handlers of hides; each one handled dried China hides at the time of infection. The preliminary report on the anthrax situation has been submitted separately.

## THE FLY PROBLEM.

Two types of disease are communicated by flies: certain blood infections may be distributed by the small biting fly of the stable; a greater menace to the health of a community are the diseases which are communicated through the contamination of food by the ordinary house fly. A recent report by the United States Public Health Service describes in detail the methods by which this is effected.

In attacking this problem the greatest progress can be made by preventing the breeding of flies. It is estimated that about 80% of house flies breed in horse manure. Breeding also occurs in privy vaults, garbage and other decomposed matter. In attempting to destroy the maggots of the house fly in manure, one must bear in mind the fact that the manure will be used for fertilizing purposes, and that the application of a strong bactericide prevents the necessary decomposition of the manure and may be directly injurious to the crops. The United States Department of Agriculture in Bulletin No. 245, issued July 20, 1915, recommended powdered hellebore as a larvicide to use in treating manure. Experiments did not reveal any injurious effects upon plants from the use of considerable quantities of this substance nor were ill effects discovered upon chickens coming in contact with the treated manure.

"Powdered hellebore should be mixed with water at the rate of one-half pound to 10 gallons and the solution thoroughly stirred and allowed to stand for several hours in a barrel or other container. In order to obtain the most satisfactory results, the manure should be sprinkled with the foregoing solution immediately on removal from the barn. The sprinkling may be done with a watering can or similar device, using 10 gallons to 8 bushels of manure, taking care that all of the hellebore comes in contact with the manure and paying particular attention to the outer edges of the pile. In estimating the amount of solution to be employed it may be assumed that two bushels of manure per horse is the daily output of the stable. This is a liberal estimate, and in many stables the daily output is much less."

The use of borax for this purpose is slightly less expensive but more dangerous to plants. The directions given for its use by the Department of Agriculture are as follows:

"Apply 0.62 pound borax or 0.75 pound calcined colemanite to every 10 cubic feet (eight bushels) of manure immediately on its removal from the barn. Apply the borax particularly around the outer edges of the pile with a flour sifter or any fine sieve, and sprinkle two or three gallons of water over the borax treated manure.

"The reason for applying the borax to the fresh manure immediately after its removal from the stable is that the flies lay their eggs on the fresh manure, and borax, when it comes in contact with the eggs, prevents their hatching. As the maggots congregate at the outer edges of the pile, most of the borax should be applied there. The treatment should be repeated with each addition of fresh manure, but when the manure is kept in closed boxes less frequent application will be sufficient. Where the calcined colemanite is available, it may be used at the rate of 0.75 pound per 10 cubic feet of manure, and is a cheaper means of killing the maggots. In addition to the application of borax to horse manure to kill fly larvae, it may be applied in the same proportion to other manures, as well as to refuse and garbage. Borax may also be applied to floors and crevices in barns, stables, markets, etc., as well as to the street sweepings, and water should be added as in the treatment of horse manure. After estimating the amount of material to be treated and weighing the necessary amount of borax, a measure may be used which will hold the proper amount, thus avoiding subsequent weighings.

"Figuring borax at five to six cents per pound in hundred pound lots, and powdered hellebore at eleven cents per pound in like amounts, and estimating the amount of manure produced by one horse per day at two bushels, these methods of treatment would cost about one cent per day per horse for borax and one and one-half cents per day for hellebore. The hellebore treatment,

however, is somewhat more effective, as it shows about 95% of larvicidal action as against 90% for borax. The efficiency of borax can be pushed up to about 98% by doubling the quantity used, but this would double the cost and increase the chance of injurious action on plants from the manure so treated."

## Correspondence.

### PREVALENCE OF TUBERCULOSIS IN MASSACHUSETTS.

Boston, July 20, 1916.

Mr. Editor: I note in your last issue, in the résumé of communicable diseases for May, 1916, that the looked-for increase in the number of reported cases of tuberculosis through the newly-established dispensaries is disappointing. While it is somewhat hard to explain this situation whereby the number of reported cases of tuberculosis has not increased despite the fact that a large number of new dispensaries have been opened, the situation is quite the reverse in regard to the applications on file at the office of the Trustees of Hospitals for Consumptives for our four state sanatoria. Ever since the opening of our newer sanatoria in 1910 up to the present time, during the summer months not only has the number of applications on our waiting list been a very small one, but in the case of women it has even dwindled to nothing, so that there have been vacant beds for women in some of our sanatoria. This year, despite the steady increase of beds in local tuberculosis hospitals, our waiting list is longer than ever before so that at the present time there are nearly 300 men, women and children waiting their turn for admission. It seems proper to let these facts be known in order to avoid giving the impression, which might possibly be gathered from the statement in your JOURNAL above referred to, that the medical profession are not active and wide awake to the necessity of seeking out the tuberculous and endeavoring to provide sanatorium treatment for them.

Very truly yours,

JOHN B. HAWES, 2d, M.D.,  
Secretary Trustees of Massachusetts  
Hospitals for Consumptives.

### APPOINTMENT.

Dr. Cecil Kent Drinker of the Johns Hopkins Medical School has been appointed instructor in physiology at the Harvard Medical School.

### RECENT DEATH

PROFESSOR EMIL METCHNIKOFF, the celebrated French bacteriologist, died of cardiac disease at the Pasteur Institute, Paris, on July 15. He was born at Kharkoff, Russia, on May 15, 1845, and was educated at the Universities of Giessen and Munich. From 1870 to 1882 he held the position of professor of zoology at the University of Odessa, but in the latter year resigned to pursue private research in the anatomy of invertebrates. In 1888 he became associated with Louis Pasteur at the Pasteur Institute, and in 1895 succeeded to the position of director which he continued to hold at the time of his death. In 1908 he shared the Nobel prize for medical research with Dr. Paul Ehrlich of Berlin. He was the author of numerous scientific works, among which may be noted "The Nature of Man," "Immunity in Infective Diseases," "Prolongation of Human Life" and "Opportunistic Essays."

### MEETING OF THE SECTION OF MEDICINE, JUNE 6, 1916.

#### PAPERS ON DIABETES MELLITUS, WITH THE DISCUSSION.

#### RESULTS OBTAINED IN THE TREATMENT OF DIABETES MELLITUS.

MAY 1, 1915-MAY 1, 1916.

By ELLIOTT P. JOSLIN, M.D., BOSTON.

In a paper read one year ago at Washington the results obtained in a series of cases of diabetes, coming under my observation for the year ending May 1, 1915, were reported, and in a subsequent paper in New York last December I brought together the results of treatment of all the cases I had seen up to that time. The former paper contained a note of hopefulness so unusual for an article on diabetes and the latter gave such specific explanation of avoidable causes of death in diabetes that now, when periods of one year and of six months have intervened, it is pertinent to inquire whether these new hopes and explanations were justified.

The comparatively short interval of time which has elapsed is by no means a bar to a correct answer, for the course of diabetes in the past unfortunately has been short, and the prolongation of life by six months to one year

would signify the gain of 10 to 30% in the duration of the disease. For, speaking roughly, the average duration of life of 408 of my fatal cases has been five years, and that of 490 of my living cases has already reached six years.

During the year ending May 1, 1915, 211 cases of diabetes came under my observation, and of this number 31, or 15%, died; during the subsequent year 314 cases were seen, and so far as I am aware, 37, or 11.7%, have died. If, for the sake of accuracy, I omit 6 cases from this number of whom I have no positive information during the five months prior to May 1, the percentage mortality is 12%, which represents a decrease in mortality over the previous year of about 20%.

TABLE I.—A COMPARISON OF THE MORTALITY OF DIABETIC CASES IN TWO SUCCESSIVE YEARS.

Periods of Observation.	Total.	Traced.		Dead.	
		No.	Per Cent	No.	Per Cent
May 1, 1914, to May 1, 1915	211	211	31	14.7	
May 1, 1915, to May 1, 1916	314	308	37	12.0	

These figures are encouraging, but they become still more so when I add that a study of the 37 fatal cases seen this last year shows that death might have been deferred in about one-half of these if the methods of treatment now in general use had been adopted.

The statistics above given are personal statistics, and therefore it appeared of interest to examine those of the State of Massachusetts, and this has been accomplished, thanks to the hearty coöperation of the Board of Health. Obviously, such compilations are less accurate; indeed, frequently the duration of the disease is not given on the death certificate. However,

for the sake of comparison I have arranged these data along with my own by decades according to the age of the individual at the onset of the disease.

TABLE II.—DURATION OF FATAL CASES OF DIABETES IN MASSACHUSETTS FOR 1915 COMPARED WITH AUTHOR'S TOTAL FATAL CASES.

Decades.	MASSACHUSETTS.		JOSLIN.	
	No. of Cases.	Yrs. Duration.	No. of Cases.	Yrs. Duration.
0-10	17	0.79	33	2.39
11-20	22	1.77	50	2.62
21-30	25	1.21	41	5.28
31-40	41	4.16	55	6.82
41-50	59	5.36	83	6.87
51-60	77	4.82	108	6.46
61-70	86	3.83	56	5.47
71-80	34	2.01	16	5.06
81-90	6	1.11	1	6.83

It will be seen that the greatest difference in mortality between the statistics of the state and my own lies in the early decades. And a further startling difference, not obvious in this table, lies in the number of cases in each group who succumbed during the first year to the disease. This is best illustrated by another table, which is of special interest because it includes the data of the Massachusetts General Hospital for two different periods. In it I have also included statistics given by Naunyn for his own practice.

TABLE III.—THE FATALITY OF DIABETES MELLITUS DURING THE FIRST YEAR OF THE DISEASE.

Sources of Statistics.	Number of Cases.	Percentage of Total Fatal Cases During First Year.	
		Number of Cases.	Percentage.
Massachusetts 1915*.....	370	27.9	
Boston 1915†.....	117	27.3	
Massachusetts General Hospital			
1824-1898.....	47	67.5	
1898-1913.....	69	40.6	
Naunyn.....	66	30.0	
Joslin.....	408	16.9	

It may not be out of place to add that of 490 cases of diabetes on my list, 94% have already passed the first year of the disease,—the danger-zone of the diabetic.

In a study of the causes of death of 408 cases of my series, it was found that two out of every three (66%) died of coma, that 87% of all those who succumbed during the first year of the disease died of coma, and that this was the case in 100% of the fatal cases in children. Therefore, if the mortality of diabetes is to be reduced, our energies should be directed first toward the avoidance of coma, because the treatment of coma is so unsatisfactory; and, second, particular attention should be exercised in the management of cases of diabetes in the first year following the detection of the disease.

\* The total number of fatal cases of diabetes mellitus in Massachusetts for 1915 was 648, but of this number the duration is recorded as less than one day in two, and not recorded at all in 278, thus leaving only 370 available for statistics; only 367 were used in Table II, three cases with duration of 22, 29 and 51 years being omitted in first three decades.

† The total number of fatal cases of diabetes in Boston for 1915 was 191, but the duration is not recorded in 74, thus leaving 117 available for statistics.

Furthermore, all cases should be persistently followed up, and the good effects of treatment not be allowed to lapse by indifference or neglect.

#### FATAL CASES.

#### DEFINITION AND DETECTION OF ACIDOSIS IN DIABETES MELLITUS.

By ALBERT A. HORNOR, M.D. BOSTON.

[From the Clinic of Elliott P. Joslin, M.D.]

SINCE KUSSMAUL described the deep breathing and coma of diabetic patients approaching death, and acetone diacetic acid and B. oxybutyric acid were associated with this condition by Petters, Gerhardt, and Minkowski, and an increase of the elimination of ammonia was pointed out by Stadelman, this state has been termed by Naunyn one of acid poisoning or acidosis.

By observation of the patient, it is easy to note the drowsiness, exaggerated respiration, and dry skin, so characteristic of the diabetic about to die in coma. So seldom does a patient recover and so temporary are the few recoveries recorded that it is manifestly necessary for us to recognize precomatose conditions if we would save our patients.

Consider the demonstrable differences between the metabolism of a comatose diabetic and the metabolism of a healthy individual. Until recently these were limited to the changes demonstrable in the urine. Of late, however, changes in the blood and in the expired air have been recognized. The changes in the urine are

the excretion of glucose and increased quantities of diacetic and B. oxybutyric acid and ammonia. The changes in the blood are a reduced amount of carbon dioxide and an increased amount of acetone bodies; the change in the expired air consists in a reduced percentage of carbon dioxide. The reason for this will be discussed later.

Among diabetics who are exhibiting no undesirable condition, one finds the condition of the urine essentially normal; in other words, an absence of glycosuria and no increased excretion of acetoacetic acid, B. oxybutyric acid or ammonia. Prior to the development of acidosis by a diabetic, there will always be a recurrence of glycosuria. Further, in none of the cases on which this study is based has there been any evidence of extreme acidosis where the amount of glucose excreted in the urine was less than the amount of carbohydrate ingested in the corresponding twenty-four hours; in other words, no extreme acidosis in the presence of a positive carbohydrate balance.

After the occurrence of glycosuria, there may quickly follow an increased urinary excretion of acetone bodies. This can usually be detected qualitatively and roughly estimated quantitatively by the addition of a few drops of a strong solution of ferric chloride (the Gerhardt test for diacetic acid, familiar to you all). It happens in rare instances, however, that a patient presents all other symptoms of diabetic coma without showing any marked ferric chloride reaction in the urine. In such instances, the presence of abnormal quantities of acid bodies may be inferred by the demonstration of an increase in the urinary ammonia, a part of the urea nitrogen being converted to ammonia, so that the acetone bodies may be excreted as salts of ammonia. In acidosis, the urinary ammonia may rise from the normal, 0.75 gr. in twenty-four hours, to 7.5 gm. or even more in twenty-four hours. At the same time, there is a change in the ammonia-nitrogen ratio of 1:12 to 1:3, or in extreme cases even 1:2. Consequently, if a twenty-four hour amount of urine be not available, one may estimate the degree of acidosis by determining urinary ammonia and urinary nitrogen and their ratio in a single specimen of urine. This, of course, involves the apparatus and ability to determine urinary nitrogen. The ammonia-nitrogen ratio serves as an index of acidosis save when alkali, for example, sodium bicarbonate, is being administered, under which condition some of the acetone bodies may be excreted in combination with the alkali administered. The determination of urinary ammonia may be done satisfactorily either by the method of Folin<sup>1</sup> or that of Malfatti.<sup>2</sup> The simpler, though less accurate, method of Malfatti (as described in the more recent text-books on physiological chemistry) is probably better adapted to the use of the general practitioner than that of Folin, involving,

as it does, only the mixture of urine with potassium oxalate and a titration with formalin. Actual quantitation of acetone bodies in urine is best done by the Schaffer-Marriott method. This, however, requires more apparatus and time than is available, save in highly specialized laboratories.

As already stated, in acidosis there occurs a reduced percentage of carbon dioxide in the expired alveolar air, which is consequent to a reduced carbon dioxide tension in the blood. Before discussing this fact, however, it is probably best to say a few words about the mechanism through which it is affected. By the micro method for quantitating acetone bodies in blood, described by Marriott,<sup>3</sup> it has finally been shown that in certain, if not all, cases of diabetic coma, there is an increase in the quantity of acetone bodies in the blood. This, however, does not affect the reaction of the blood either by increasing acidity or, what would be the same thing, decreasing alkalinity, though all the acetone bodies are acid in character. The present conception of the wherefore of this fact is chiefly due to the work of Dr. Lawrence J. Henderson.<sup>4</sup> His studies have shown definitely that the relation of blood to neutrality is that of slight alkalinity, and varies only within extremely narrow limits, and is capable of accurate determination only by the use of electrochemical methods. The reaction of the blood is maintained by the large amount of weak acids and their salts in the blood,—carbon dioxide and sodium bicarbonate, monosodium phosphate and disodium phosphate, and somewhat by the amphoteric acids from proteins. Carbonates and phosphates possess, so far as is known, the highest power to preserve neutrality in solution. Under normal, as well as under abnormal, conditions this is quite essential, for acid substances are continuously being poured into the blood in the course of normal metabolic processes. The maintenance of neutrality of the blood is further facilitated by excretion of volatile acids through the lungs, chiefly in the form of carbonic acids and the excretion of non-volatile acids through the kidneys, chiefly in combination with ammonia and other bases. Under normal conditions, the amount and kinds of acid poured into the blood by metabolic processes are such that the amount of carbonic acid present in the blood is practically constant. The acetone bodies in the blood of diabetics may be and frequently are in such great quantities that in order to maintain its constant relation to neutrality the blood must lower the normal tension of other acids. This is done by lowering the tension of carbonic acid. To do this, more carbon dioxide must be excreted through the lungs, inasmuch as carbon dioxide is excreted from blood capillaries until, and only until, the carbon dioxide tension and alveolar air is the same as that of the blood, it is necessary to increase lung ventilation. This

has been shown to be regulated by the reaction of the blood. In other words, lung ventilation will keep carbon dioxide at a level necessary to maintain the normal reaction of the blood. It was reasoned, and later shown, that since carbon dioxide is excreted from blood into alveoli up to the point where the tension of carbon dioxide in alveoli equals the tension of carbon dioxide in blood, the estimation of carbon dioxide tension in expired alveolar air would furnish an estimate of the tension of carbon dioxide in blood and, consequently, an indirect estimate of quantity of acetone bodies in blood. Recently, Van Slyke, Stillman, and Cullen<sup>2</sup> of the Rockefeller Institute have devised a method of determining directly the carbon dioxide tension of the blood. Theirs is an admirable and accurate method and requires no cooperation on the part of the patient and, consequently, is suitable for use even in comatose patients. The method is easily learned, but requires considerable apparatus and more time than does the estimation of carbon dioxide tension in alveolar air, which has been found to run parallel, at least among diabetics.

For the determination of carbon dioxide in alveolar air many methods have been described. In 1914, Boothby and Peabody, after careful study of the various methods, recommended that of Plesch as modified by Higgins, the collection of sample being simple, but requiring considerable apparatus for analysis of gas collected. Quite recently Marriott<sup>6</sup> has described a method which is probably simpler than any other, when once the standard solutions have been prepared. The method employed in this work has been that described by Fridericia.<sup>7</sup> The method is simple, involves the use of inexpensive apparatus, which may be easily transported to the bedside, and the complete test requires less than fifteen minutes. The objection raised to this method is that it requires cooperation on the part of the patient. This is, of course, regrettable, but among diabetics who cannot cooperate, the clinical evidence of acidosis is so striking that an estimation of carbon dioxide tension would be desired only for academic reasons. On the other hand, observations made upon one comatose patient agreed with that obtained by direct determination of carbon dioxide tension in the blood.

The determination is made by collecting in a specially constructed U-shaped glass tube the last hundred cc. of a forced expiration after a normal inspiration, and then absorbing at room temperature the carbon dioxide in this 100 cc. of expired alveolar air with a strong alkali (20% potassium hydrate), thereby causing a partial vacuum, which is later replaced by water at room temperature and atmospheric pressure. (A detailed description of apparatus and method is appended.)

By a study of the carbon dioxide content of alveolar air it is found that normally the ten-

sion of carbon dioxide varies between 38 and 45 mm. of mercury. Among diabetics with slight acidosis, the carbon dioxide tension varies between 32 and 38 mm. of mercury; with moderate acidosis between 28 and 32 mm. of mercury; severe acidosis less than 25 mm. of mercury. Nineteen mm. of mercury is the lowest tension observed in a patient ultimately recovering from acidosis. Nine mm. of mercury is the lowest observed in this present study. That was in a comatose patient only a few hours ante mortem.

In an analysis of three hundred observations of carbon dioxide tension in alveolar air recently made upon cases from Dr. Joslin's Clinic, and reported by me at the Peter Bent Brigham Hospital, it was found that patients with carbon dioxide tension less than 25 mm. of mercury all had three grams or more urinary ammonia in twenty-four hours, and a negative carbohydrate balance. When the carbon dioxide tension varied between 25 and 33 mm. of mercury, urinary ammonia was between 3.7 gm. and 1.5 gm. in twenty-four hours, and in three-fourths of the cases the carbohydrate balance was positive. With carbon dioxide tension greater than 33 mm. of mercury, the urinary ammonia in twenty-four hours was less than 2 gm. The carbohydrate balance was usually positive and always so when the carbon dioxide tension was above 36 mm. of mercury. Ferric chloride reaction varies from negative to strongly positive at 36 mm. tension and also at 23 mm. tension, and, consequently, must be a very rough index of the degree of acidosis.

With the determination of the so-called alkali tolerance as an index of acidosis by the administration of sodium bicarbonate until the urine becomes alkaline, I have had no experience. This has been due chiefly to the fact that this study has been made entirely within the past year, and that now some of us are in doubt as to whether administration of alkali may not do harm. Consequently, it has not been deemed right to attempt a study of this sort from a purely analytical standpoint.

In conclusion, therefore, the acidosis of diabetes mellitus, aside from its clinical picture of exaggerated respiration, drowsiness and rapid pulse, may be defined as a condition in which the carbon dioxide tension in the blood and, consequently, in the alveolar air is reduced; the acetone bodies in the blood and urine are increased and associated with this is a rise in the excretion of ammonia; glycosuria is marked, and, saving exceptional cases, toward the end of prolonged coma, the carbohydrate balance is markedly negative. All these factors are important in determining the degree of acidosis, and, where time and facilities permit, should be ascertained. The detection of glycosuria, the demonstration of a positive ferric chloride reaction, and the determination of a diminution in the alveolar carbon dioxide tension are the procedures suitable for

bedside use. The carbohydrate balance is also a valuable indication and one surely to be determined, but, unfortunately, it must always furnish information in part, at least, a day late.

## APPENDIX.

*Fridericia Method.* This method possesses the advantage of being simple and involving the use of apparatus which may be easily transported to the bedside. One hundred cubic centimeters of alveolar air are collected in a closed chamber and then cooled from the temperature of the body to that of the room. The carbon dioxide in this air is then absorbed with a 20% aqueous solution of potassium hydrate, thereby creating a partial vacuum, which in turn is equalized with water. This water is then subjected to atmospheric pressure, when the amount of carbon dioxide replaced by water can be read in per-

centage of atmospheric air by reading the height in centimeters to which the column of water has risen in the closed 100 cc. chamber. This percentage may be changed to millimeters of mercury pressure by multiplying by the difference between barometric pressure at the time of the test, and this varies in Boston between 770 mm. and 750 mm., and the tension of aqueous vapor at 37.5° Centigrade, which is 48 mm. mercury. This will make a factor which lies between 718 and 702. As the reading of 760 is much the more common at sea level, for clinical purposes the factor 715 may be used satisfactorily. The

patient should be in the same position and quiet for ten minutes prior to the performance of the test.

After a normal inspiration, the end, A, of the apparatus is inserted between the lips, and the patient is instructed to expire forcibly through the apparatus, with cocks C and D open, so that there is a free passage from A to B. The tube remains in the mouth throughout the entire expiration and the cock C is then closed, thus retaining between cocks C and D the last 100 cc. of expired air. (As the exchange of air in the upper respiratory passage is 200 cc. and the exchange of air from the alveoli is 800 cc., it is plain that with any care at all a sample of alveolar and not upper respiratory air will be obtained.) The apparatus is now immersed in a glass tank of water at room temperature and allowed to remain there five minutes. The best way to obtain water at room temperature is simply to keep the glass tank in the room with the patient for several hours before the test, though with an ordinary thermometer one can easily adjust the temperature of the water to that of the room. At the end of five minutes about 10 cc. of 20% aqueous solution of potassium hydrate is poured into the apparatus through the orifice B. A little of this potassium hydrate will leak through the hole in cock D to chamber CD. Now cock D is turned to the left so that chamber CD is closed and chamber BD is also closed. The small amount of potassium hydrate in chamber CD is shaken in the chamber for a moment. Then with apparatus in upright position, cock D is turned so that there is a continuous passage from C and B, and the amount of potassium hydrate which will run into the chamber CD is allowed to do so. Now cock D is turned to the left until BDE is a continuous passage, and in this way potassium hydrate is allowed to escape into the water tank. Chamber CD still contains 2 or 3 cc. of potassium hydrate solution and should be thoroughly washed with this solution. Every point in the surface of chamber CD must be touched by the alkaline solution. This is accomplished by shaking very thoroughly the potassium hydrate in chamber CD. The apparatus is again immersed in the tank of water, cock D is turned to the left until water rises into CD through EDC, and the apparatus left in the water five minutes. At the end of this time, the apparatus is raised until the bottom of the meniscus of the water in chamber CD is level with the top of the water in the tank. Now cock D is turned to the right until water runs through EDB to the level of water in chamber CD, which is now closed. Then cock D is turned further to the right until CDB is a continuous chamber. The apparatus is then again immersed to the bottom of the glass tank and the water in the arm BD of the apparatus should be at the same level with the water in the chamber CD and continuous with it. If this is not so, then the amount of water in BD should be changed

until it reaches the height of the column of water in CD. The reading is now taken in centimeters of the height to which the column of water stands in CD, and this is so graduated as to represent the percentage of  $\text{CO}_2$  which was absorbed by alkali and replaced by water. This completes the test.

The apparatus is prepared for the next test by opening cock C so that A to B is a continuous passage. The fluid in the apparatus is allowed to escape. Orifice B is put under the faucet and cold water allowed to run through the apparatus, taking care to shake sufficiently at the time so that water touches all of the inside of the apparatus. Repeat. Then pour through orifice B about 10 cc. of 4% solution boric acid. Rinse the apparatus very thoroughly with the acid so that there shall be no alkali remaining adherent to its sides. Wash again with cold water. Leave the apparatus so that orifices A and B are down, thereby allowing any water in the apparatus to drain out.

From the above it will be seen that the apparatus necessary is, first, the Fridericia appliance, a glass tank, whose depth is equal to the length of the Fridericia apparatus, a wash bottle containing 20% solution of potassium hydrate and another wash bottle containing 4% solution of boric acid. It is convenient to add an indicator, such as alizarin, or litmus, to the alkaline and acid fluids.

#### OBSERVATIONS ON THE BLOOD SUGAR IN DIABETES MELLITUS.

By ORVILLE F. ROGERS, JR., M.D., BOSTON.

[From the Medical Services of the Massachusetts General Hospital.]

THE aim of this paper is to present some conclusions as to the value or necessity of determining the blood sugar in treating diabetes, either from a prognostic or therapeutic standpoint.

There have been in the past many methods for the estimation of blood sugar, but most of them have necessitated the use of such large quantities of blood that they were not practical for frequently repeated determinations, and therefore not suitable for clinical work. Another objection has been the complicated procedures involved, capable of being carried out only in a well equipped laboratory, and by a trained chemist. In the past few years there have been a number of methods brought forth which can be carried out on small samples of blood, notably the Bang micro-method,<sup>1</sup> in which the amount necessary is only a few drops, and the Lewis-Benedict method,<sup>2</sup> in which 2 cc. of blood are required. At the Massachusetts General Hospital we are using the Lewis-Benedict method\* with a modification described by Myers and Bailey.<sup>3</sup> There are several other modifications

in which only a few drops of blood are used, but the accuracy of these is rather doubtful.

The normal blood sugar varies between 0.06% and 0.11% according to the various authors. With the method that we use, the average is around 0.09% to 0.10%, and the high limit of normal about 0.11%. There are many factors that influence blood sugar besides diabetes. The sugar in the blood seems to be in a very labile state, and may be much influenced by a number of causes. Excitement, infections, the ingestion of food, and nephritis may all raise the blood sugar values above normal for a greater or smaller period of time, and to a greater or less degree. Lately the influence of damaged kidneys in raising the blood sugar in both normal and diabetic individuals has been emphasized more and more.

Diabetes is the most common cause of increased blood sugar and it also causes the highest values. Those rather rare cases of renal diabetes are the only ones in which there is not some elevation of the blood sugar while sugar is being excreted.

The blood sugar among those patients treated at the Massachusetts General Hospital who had diabetes but who had had no previous treatment, or whose treatment had not been efficient, that is, they were still excreting considerable sugar, was about 0.26% for an average, with variations from 0.76% to 0.16%. The highest value that was found (0.76%) was in a man in coma and the next highest was 0.36% in a very severe diabetic on the verge of coma. Values above 0.30% seem to be uncommon unless there is some difficulty on the part of the kidneys in accomplishing excretion.

On the other hand, the blood sugar determinations done on patients at the time they left the hospital, when they were sugar-free, and had been so generally for some days or weeks, showed variations from 0.07% to 0.18%, and averaged 0.12%. This is a decided drop in the blood sugar, but only six or seven of the values were actually within normal limits.

This brings up the question of the relation of glycaemia to glycosuria, and the permeability of the kidneys to sugar. The level of sugar in the blood does undoubtedly determine in a general way in normal or diabetic individuals, with normal kidneys, the presence or absence, or the amount, of glycosuria, but it is also true that the level which blood sugar must reach in order to cause a glycosuria of any given intensity varies greatly in different diabetics and in the same diabetic at different times. Recent work by Hamman and by Foster reported at Washington in May, 1916, seems to show that for normal individuals there is a fairly constant threshold for sugar excretion. However, for diabetics this threshold was more variable.

McLean,<sup>4</sup> Epstein,<sup>5</sup> and Myers and Bailey<sup>3</sup> have published papers tending to show a direct relationship between glycaemia and glycosuria, especially when there is no renal element, and

\* I wish to express my thanks to Dr. W. Denis and Miss Anna Minot, by whom almost all of the determinations have been done.

they have all emphasized the fact that where the kidneys are damaged, either by nephritis or in coma, this relationship is much disturbed and we may have freedom from glycosuria with a hyperglycaemia of considerable proportions, due to the raising of the threshold of sugar excretion. This, of course, can be determined only by estimations of the blood sugar, and it is in this type of case that we may get some information of practical value from the blood sugar determinations.

In persons in coma, excretion both of sugar and of acid bodies may be much interfered with, and in the severest cases the urine may not give a reaction for either of these substances, or the reactions may be very slight. The blood, on the other hand, may have very large amounts of these substances, and it is through blood examinations alone that a true picture of the condition may be arrived at. In other cases, when nephritis is present, the urinary excretion of sugar may be much diminished in proportion to the hyperglycaemia, and the latter may remain quite elevated after the glycosuria has ceased. Likewise in some diabetics with normal renal function, as measured by our usual tests, there is apparently a decreased permeability for sugar alone, giving rise to the same state of affairs.

The true influence of this persistent hyperglycaemia on the diabetic state is not definitely settled. If there is a sufficient excess of sugar circulating in the blood of a diabetic without nephritis to cause glycosuria, it is assumed that there is an overstrain on the pancreatic function, and that the latter will be thereby weakened. If nephritis is added to this, and the glycosuria thereby prevented, the hyperglycaemia persists as before. The question now is as to whether under these conditions the functional overstrain still continues to be placed upon the pancreas.

The answer from general grounds would appear to be "yes," but there are some things that argue against this. Allen,<sup>6</sup> by repeated injections of dextrose into a normal animal, sufficient to keep up a continuous glycosuria and hyperglycaemia for many months, was unable to produce diabetes; on the other hand, the animal's tolerance for dextrose became doubled, probably due to decreased permeability of the kidney for sugar. With animals, partially depancreatized, but not rendered diabetic, he was unable to produce true diabetes by means of these injections. The other argument against the evil effects of a persistent hyperglycaemia is based on clinical grounds, namely, that many patients who have had this condition while in the hospital have done very well in the out-patient department, though, to be sure, we do not know that their hyperglycaemia had not disappeared. In a great majority of the cases the treatment as carried out with the urinary sugar alone as a guide seems to be efficient in reducing the blood sugar to within a slight amount above normal, and the

blood sugar determinations are not necessary as a guide.

From a prognostic standpoint it is not possible to predict from a patient's initial blood sugar level how long it will take him to become sugar free. Two parallel cases, each with a blood sugar of 0.26% on a mixed diet, entered within a week of each other recently. One had 6%, and the other 5% sugar in the urine. One became sugar free after one and a half days of low diet, and the other required three days of low diet and three days of fasting to achieve the same result.

As to the height of tolerance as forecast by the blood sugar, there seems to be nothing more definite. The tolerance may be low when the initial blood sugar is low, or it may be high when the admission blood sugar is also very high. In the same way, the fact that the blood sugar reaches normal values after treatment does not necessarily mean that the case is mild, for there have been several cases treated in which the tolerance was quite low in spite of easy reduction of the blood sugar to normal. On the other hand, there have been cases with fairly high tolerance whose blood sugar showed a tendency to be quite elevated even after some weeks of treatment, and this without high blood pressure, albuminuria, low renal function (phthalein test), or casts. To be sure, most of the patients who showed this persistent hyperglycaemia had some evidence of renal trouble as revealed by one or more of the four criteria mentioned.

As has been pointed out before, we do not know definitely how much, if any, harm it does a patient to live with a continued hyperglycaemia, so until we do the value of blood sugar determinations as a prognostic aid seems doubtful. Even in cases without renal involvement there does not seem to be any definite correlation between either the initial or the final blood sugar and the tolerance, but in general the mild cases tend to sink to normal faster and more easily than the severe, though, as shown, there are many exceptions to the rule.

One point that should be borne in mind in relation to these determinations is that they must be done either with the patient fasting in the morning, or at least four or five hours after food, for the alimentary hyperglycaemia of diabetes is of considerable duration and extent.

Many writers have pointed out that blood sugar is in a very unstable state, and if only a single determination is done, a false picture of the condition may be obtained. It would undoubtedly be best to have daily determinations if one wished to follow the blood sugar accurately.

#### SUMMARY.

Diabetics have a higher blood sugar when they are excreting sugar in the urine than they do when the urine is rendered sugar-free.

## EXPLANATORY NOTES.

Blood for sugar determinations was taken in the morning with the patient fasting, and precipitated promptly, except in two instances, when the samples were taken three to four hours after a light breakfast, as noted below.

Pipets are indicated as "mixed," either when the patient had not had a restricted diet, or when the restrictions had been lax, or not observed.

When the carbohydrate in the diets was not known definitely that fact is indicated by a "±" sign, or by giving the probable limits, as 80/100.

In some instances the maximum limit of tolerance was not determined, as the patient had to leave the hospital. This is indicated by a "+" after the figure given, which is the limit reached in the wards.

Many of the admission blood sugar determinations were done when we did not have the corresponding 2-hour urine, so the total output of sugar cannot be given.

The urinary sugar is determined by the Benedict Methods both qualitatively and quantitatively.

\* The sample was taken when the patient returned to the Out-Patient Department, and was about four hours p. c.

† A. C. (about three hours p. c.)

This patient left the hospital on Mar. 17 but returned to the Out-Patient Department on Mar. 24, with 4.5% sugar in the twenty-four hour specimen. He at once returned to the hospital and was treated. The single specimen of urine, Mar. 25, showed only 0.8% sugar, but his blood sugar on that date still showed the effects of his previous overeating.

\* P. c. 14 grams sugar in twelve hours. Afterwards was incontinent.

The threshold of sugar excretion varies in different diabetic individuals, and apparently in the same individual at different times.

Sometimes the blood sugar returns to normal under treatment, and this is generally in the milder cases, though there are some exceptions to the rule.

A persistently elevated blood sugar may be an indication of the greater severity of the disease, or it may occur in apparently mild cases, but generally associated in the latter instances with some renal impairment.

By keeping the carbohydrate intake well below the limit of tolerance, as shown by the appearance of glycosuria, it has been found that the blood sugar will almost, if not quite, sink to normal, and our experience leads to the belief that efficient treatment can be carried out in most instances using the urinary sugar alone as the therapeutic guide.

There are undoubtedly a certain number of severe cases with marked acidosis or nephritis in which the true picture of the condition is much illuminated by direct blood examinations, both for sugar and alkali reserve.

#### DISCUSSION.

DR. HARRY W. GOODALL, Boston: Dr. Joslin emphasizes the importance of early treatment of diabetes. I feel very strongly that in the absence of any other diseased condition the duration of life must necessarily depend in a large measure upon the intelligent early treatment of the patient.

One is very much impressed by the importance of early treatment in studying the out-patient cases. For the past seven years I have taken charge of all the diabetes in one of the out-patient clinics, and during the last two or three years the present method of treatment has been followed out as carefully as it is possible for one to carry it out. The conditions in the out-patient clinic are not unlike the conditions that one meets with in private work, especially the general practitioner.

The improvement in the treatment is most striking. Up to within the last two or three years the treatment was more or less spasmodic. We had little control of the patient, and the results were not especially satisfactory. At the present time with a clinic of about sixty diabetes, the majority of whom represent the early cases, the patients are grouped together into a class, being treated as a class and treated

individually. All of the patients are under the control and direct treatment of the young woman who has been trained in the treatment of diabetes, and is not a medical person. She is under my own supervision. Out of the sixty patients there have been but two deaths, which I think were the result of dietetic errors. In both instances it seemed impossible to get the proper food for the patient. Of course it is only fair to say the most severe cases were sent to the hospital for treatment, and then after they had become sugar-free were sent back to the clinic, but during this period of two or three years all the patients have been able to carry on their daily activities. The greater part of the time they have been free from sugar, and there have been few, if any, recurrences.

One of the most interesting things has been the treatment of the male cases. It has been very difficult to get hold of the men. They will not give up their work to come to the clinic, and we have succeeded in getting the mothers or the wives, and they have come for directions and have carried out our instructions at home. Out of the sixty cases about ten patients have paid little or no attention to the treatment whatever. They would come spasmodically, as they did in the days of old, but the remaining forty-five or fifty have attended most diligently, and have tried in every way to carry out our treatment and suggestions.

I think the success of the clinic has depended entirely upon the young lady in charge. She has shown great patience. When sugar has returned she has taken pains to find out what caused the return of the sugar, whether it was the fault of the patient or fault in the preparation of the food or what-not, and instead of scolding the patient, has gone all over the subject again and has taken every possible pains for encouragement in the work.

Whenever questions have arisen or whenever new patients have come with diabetic complications, they are immediately taken to the class and demonstrated as a warning of what will happen to them if they don't follow instructions. Under this system we have had the most satisfactory results, and I am sure even more satisfactory to the patient than to the physician.

DR. WALTER R. BLOOR, Boston: Because of the practically universal belief that diabetes is a disorder of the carbohydrate metabolism, the fact that there is a disturbance of the fat metabolism at the same time has been rather lost sight of, although some of the important symptoms of diabetes—for example, acidosis—are due, without question, to the disturbance in the fat metabolism. One reason for the failure to take the fats into account is no doubt the fact that glycosuria is the symptom which is readily recognized and measured. There are plenty of methods for determining the sugar in the urine, while there has been no satisfactory

or simple method for determining the fat; also the sugar is excreted while the fat is not, or at least we don't know of any fat secretion. A number of conditions indicate a disorder of fat metabolism. Whether the primary disturbance is a disturbance of the fat metabolism or of the carbohydrate metabolism is still a question.

In many diabetics obesity is a beginning sign, that is, obesity precedes the glycosuria. From fifteen to forty-five per cent. of diabetics begin with obesity. Then there is the ever-present symptom, acidosis, which is almost certainly due to failure to burn the fats. And, third, there is the lipemia, that is, the milky appearance of the blood, due without doubt to finely suspended fat.

This lipemia was a very common symptom in the days of the protein-fat treatment for diabetes, and a great deal of stress has been put on its presence by certain physicians, particularly in Germany. Inasmuch as the first stages of fat metabolism are believed now to take place in the blood, I considered it a great opportunity when I was allowed to examine the fat in the blood of Dr. Joslin's cases of diabetes. I found in the main two things: In mild diabetes there is practically no change in the fat of the blood. In severe diabetes the blood fat may be increased to 100 or 150%. This increase in blood fat includes not only what we ordinarily call fat, that is, glycerides of the fatty acids, but also "lecithin" and cholesterol. It is quite remarkable, it seems to me, that the relations between these constituents are practically those of the normal conditions. They are all increased together, and the relationships between them are not changed. This would seem to me to indicate that the fat metabolism in these cases under this treatment is practically normal, although on a higher plane. Under normal conditions the fat metabolism proceeds with a relatively low concentration of these fat constituents. In severe diabetes it requires a much greater concentration to, so to speak, push the reaction to its completion.

The other point which I wish to mention is that in Dr. Joslin's patients there was no lipemia, that is, the blood plasma was in all cases perfectly clear. For this reason I am disposed to regard lipemia as due to a fault in feeding,—that in the cases where it appears too much fat is being given. One point of Dr. Joslin's treatment is the regulation of the fat early in the treatment, and I believe that the disappearance of the lipemia is due to this fact, and that if lipemia is present it means simply that the patient is getting too much fat. There is no question that the fat metabolism is disturbed in diabetes, and if the lipemia occurs it means simply that the patient is getting more fat than he can take care of, even if he is getting only ten grams a day.

DR. G. CARROLL SMITH, Boston: I would like to call attention to one or two things which I

think we are in duty bound to mention and might be neglected by somebody else if I didn't call attention to them. I feel, for one, and I know from personal contact with many of you gentlemen that we all feel greatly indebted to Dr. Joslin and his co-workers for the admirable work that they have been doing for a number of years to help clarify the subject of diabetes, and I know you will all be glad to hear, if you have not already read, that in very many of the American cities the Joslin system is now in vogue, and especially is this true in the city where very advanced medical work is being done, namely, Chicago. The work being done today in the Cook County Hospital is entirely based on Dr. Joslin's system, and careful records are made according to his suggestions and according to the papers which he has read heretofore describing clearly the manner of procedure.

One other point which I think we ought to bear in mind today is that Dr. Joslin is fairer in his consideration of statistics than has usually been customary with medical men. As a matter of fact many of these cases that enter into his statistics are comatose when he first sees them, and of course we all know that such cases should not enter a table of statistics from any rational standpoint. There are other factors besides acidosis that come into consideration in a discussion of the cure of diabetes, because many diabetics die of other complications fundamental to the diabetes itself. The final acidosis undoubtedly is due to the faulty metabolism of fat in most cases, but it may be also in many cases due to defective circulation, as seen in cardio-renal disease. Such cases seem fairly to belong under the head of symptomatic, rather than idiopathic diabetes in the compilation of Dr. Joslin's statistics. Therefore, the high mortality of the same need not be discouraging.

A MEMBER: I would like to ask a question of Dr. Joslin,—how he knows when he has a case of diabetes how long the duration of the disease is; whether he considers the statistics throughout the state of any real value, when most of us have to guess at the duration of the disease when we make out the death certificate.

THE CHAIRMAN: I hope Dr. Joslin may be able to reply to that question. That is the only question I wanted to put to him,—when they speak of a case of diabetes of one year's duration, or six months', how have we any idea what the duration has been before the patient comes to us?

A MEMBER: I would like to ask Dr. Joslin if he can tell us what he does by way of treatment, or how he manages the diet.

THE CHAIRMAN: I would say in defence of Dr. Joslin that we didn't ask him to go into the question of treatment, as that would be a long subject. He has picked out just a little special

point in the treatment of a large number of cases.

THE CHAIRMAN: As we are not to have the pleasure of hearing from Dr. Janeway, I would like to give you a very few statistics taken from an article published by Dr. Janeway, these statistics being taken from a large number of life insurance companies. Life insurance companies, of course, look upon life merely as a matter of dollars and cents. The statistics are really quite interesting. The average blood pressure in nearly three thousand cases between thirty and forty was 123 to 128; between forty-five and sixty it was 128 to 134. Now, in 2600 cases accepted with a blood-pressure of 142 the average mortality was that of all cases. Of 525 accepted with a blood-pressure of 152 the mortality was 30% up. Of 1970 rejected, with a blood-pressure over 160, the mortality was almost double. I acknowledge that these figures were perfectly startling to me, but such they are quoted from a large life insurance company of New York.

DR. JOSLIN (closing the discussion): A question has been raised, Mr. Chairman, about the treatment. I will just pass around some of these cards to show the methods that several of us have adopted here. In the second place, about the statistics, that is an excellent point that was raised. I shall be very glad to answer it. For example, the total number of fatal cases of diabetes mellitus in Massachusetts for 1915, for which you gentlemen signed death certificates, was 648; but unfortunately the gentlemen here and elsewhere in the State did not record the duration of the disease in 278 cases at all, and in two cases recorded it as less than 24 hours, so only 350 to 370 cases were available for statistics, even a still smaller number than that as shown by the footnote I have used. Any statement about statistics of the duration of diabetes would be open to serious question. It is very difficult to say. In Boston, for instance, I think nearly one-half of all the cases that are recorded of deaths from diabetes had to be thrown out in making up the statistics because no duration whatever was put down. It is an important thing to endeavor to find out what the duration is, because that gives us some idea to go by as to treatment. As to the onset of a case of diabetes, sometimes you can tell, sometimes you can't. In a considerable number of cases it comes on acutely. For instance, out of my list some eighty odd cases were discovered by life insurance. On the other hand, in a good number of the cases the history showed the absence of sugar in the urine quite a long time before the disease was discovered.

A word about mortality. It really is the fact, as Dr. Smith pointed out, that a large number of cases that die are severe when one first sees them. Of course I see a great many cases of that kind for the first time. This last year one died of cancer, two of gangrene, one of appendi-

citis. To Dr. Bloor we are specially indebted for his painstaking work about the fat. I think few of us realize that a painstaking analysis takes about three hours, and that the fat is an extremely important matter, in fact the key to the situation of acid-poisoning today; and we are very fortunate here to have Dr. Bloor, who stands perhaps first in the world in the work along this line, investigate this problem.

To the other gentlemen, too, I am sure you, with me, are much indebted for their painstaking research work. It takes a great deal of time to carry through these blood analyses. They are easy to describe, but it is hard work, and what comes from hard work counts in the end.

A MEMBER: How does age affect the mortality?

DR. JOSLIN: All these data about mortality I have written up in extensive form, and I have really gone into it in great detail. For instance, all the cases have been classified according to the mortality, according to the onset of the disease. For example, in 1050 cases they are classified by mortality, and then one group taken up after another in really very great detail.

## PAPERS ON NEPHRITIS, WITH THE DISCUSSION.

---

### TESTS OF RENAL FUNCTION FROM THE STAND-POINT OF THE GENERAL PRACTITIONER.

BY FRANCIS W. PEABODY, M.D., BOSTON.

[From the Medical Clinic of the Peter Bent Brigham Hospital, Boston.]

DURING the past five years the attention of a large group of research workers in clinical medicine has been devoted to the development of tests of the functional capacity of the kidneys. Many methods have been devised, and exhaustive studies, both experimental and clinical, have been carried out to determine the comparative value and significance of the various tests. There has resulted a mass of new and important information which forms a landmark in the progress of scientific medicine, and which throws much light on the pathological physiology of nephritis. In a comparatively short period so much definite advance has been made that the time has now come when it is fair to take stock of our knowledge and to attempt to determine wherein and how far it is of direct benefit to the practitioner of medicine. In so doing it will be well to consider first the general significance of renal function tests, and second, the relative value of the various methods which have been suggested.

It is important to appreciate that these tests

are intended to be indices of impaired function. They are in no sense primarily diagnostic measures, although in certain conditions they may assume a diagnostic significance. Until the efficiency of the kidneys is decreased to the extent that they are unable to perform their excretory functions in the normal manner, the tests give, for the most part, no evidence of renal disease, and, on account of the great "factor of safety" with which all the organs of the body are endowed, there may be a very considerable destruction of renal tissue without impairment of renal function. The early diagnosis of nephritis must continue to be based, as heretofore, chiefly on the clinical history, the physical examination, the blood pressure, and the general characteristics of the urine. It was hoped that those functional tests which consisted in determining the ability of the kidneys to excrete certain definite substances (urea, lactose, salt, water) might be of value in the differential diagnosis of various morphological types of kidney lesion, but, unfortunately, careful study of the post-mortem findings has failed to reveal a constant relationship between inability to handle the test substances and any specific anatomical renal condition.

Broadly speaking, the chief value of the renal function tests lies in the field of prognosis. They give an index of the severity of the case, provided that it is so advanced that there is already functional impairment as well as anatomical involvement of the kidneys. They may frequently give the first and only indication of a very serious condition which is masked by a physical examination showing nothing alarming, and a urine examination which is only slightly abnormal. They serve as guides as to the progress of the case from month to month, and thus incidentally aid in directing treatment. They are, moreover, often of the greatest practical value when they give no positive information beyond the fact that the functional capacity of the kidneys is normal. This permits the giving of a prognosis which is, temporarily, at least, favorable, and which is based more securely than it could be by any other means.

However, few laboratory tests in clinical medicine are absolutely specific, and even in considering the prognostic value of the methods for the determination of renal function there are certain exceptions which must be taken up. The group of cases in which the tests have proved themselves to be of the most practical value is that which consists of chronic nephritis associated with vascular hypertension and cardiac hypertrophy, the type of case usually classed as chronic interstitial nephritis, or arteriosclerotic kidney. This is, of course, the most common form of chronic nephritis in clinical practice. In that other group of cases, usually marked by great oedema, oliguria, absence of cardiac hypertrophy, low blood pressure and large amounts of albumin in the urine,—the type generally

referred to as chronic parenchymatous nephritis, the functional tests are of much less significance. Even in extremely late stages of the disease all of the functional tests may be normal, or atypical. It is perhaps fortunate from our present point of view, that it is exactly in this group of patients that the prognosis can often be made with considerable accuracy from the other findings in the case. It should, moreover, be mentioned that in even the group of hypertensive cases there are occasional instances in which it has been impossible to correlate the functional tests with the clinical condition. Such atypical findings have occurred with all the tests that have been extensively used. Sometimes they are the result of a single observation and may be due to faulty technique; sometimes they may be due to errors inherent in the method; at other times they may depend on temporary variations in renal function which are not, however, true indices of the condition of the kidney. In cases with cardiac failure, all the tests in which the urinary output is a factor are liable to give unsatisfactory results, and it is only after compensation has been restored that an accurate picture of the renal condition is obtained. The same is true of local conditions of the urinary tract which interfere with the excretion of urine,—such as renal calculus and prostatic hypertrophy. Finally, of course, these tests have but little bearing on the prognosis with regard to what may be considered the accidental complications of chronic nephritis,—such as cerebral hemorrhage and cardiac failure.

The number of methods that have been proposed for the determination of the functional capacity of the kidneys is large, but the majority of them can be easily classified into a few groups, depending on the general principles involved.

There is thus one type of test which depends upon the analysis of blood. Owing to the inability of the kidneys to excrete the normal products of metabolism at the usual rate, these substances may accumulate in the blood, and the amount to which they are found to have increased in the blood serves as a general index to the degree of disability of the kidneys. The substances which have been most thoroughly investigated are the total non-protein nitrogen, urea, creatinin, and uric acid. Practically speaking, the two former, non-protein nitrogen and urea, are the substances which have attracted special attention. It was recognized many years ago that these substances are increased in the blood in chronic nephritis, but exhaustive studies of the conditions determining the increase, its relation to the clinical picture, and the variations which may result under different influences have been possible only since the simplified and rapid methods of Folin and of Marshall have made possible the obtaining of accurate analyses with small amounts of blood. The practical value of the non-protein nitrogen or the urea in the blood as an index of renal func-

tion is often great, but recent investigations have brought to light certain conditions under which the results may be quite misleading.<sup>1</sup> Thus, for instance, the normal values are much more variable than was at first supposed to be the case, and many healthy persons on a moderately high protein diet will have a urea content of the blood, which, under other circumstances, might suggest a considerable degree of nephritis. On the other hand, the level of these substances in the blood of persons with chronic nephritis may be markedly affected by diet, and figures which are well within normal limits may be found in patients with severe kidney lesions, provided they have been for a period on a low protein diet. Variations in diet may thus cause changes in the blood analysis, which are wholly independent of the actual state of the renal function.

Since the demonstration by Widal of the close relationship between sodium chloride excretion and the production of edema, and of the association of chloride retention with chronic parenchymatous nephritis, much attention has been paid to salt retention as an index of renal function. Few definite facts, however, of clinical importance, have as yet resulted. It is at present generally held that the metabolism of sodium chloride is so complicated, and so readily influenced by factors which are not yet understood, that a great deal of study is necessary before salt determinations in either blood or urine will assume a practical significance in the determination of renal function.

Another group of methods consists of those in which definite amounts of various substances are fed to the patient, and the rate of their excretion determined by means of urinary analysis. Typical of these is the test in which nitrogen, in the form of urea, is added to the usual diet. By quantitating the nitrogen in the urine, it is possible to determine whether this added nitrogen is excreted by the kidneys, and whether or not it is excreted within the time limits that might be expected in a normal individual. The successful application of such tests involves having the patients on a constant standard diet for several days before and after the test is given, the collection of accurate twenty-four hour amounts of urine, and the careful analysis of the urine for nitrogen. The results obtained are hardly to be regarded as quantitative, but rather as gross indications of renal function. Moreover, the number of days required, and the necessarily strict control of diet and urine, make it almost impossible to carry out these tests except under the best hospital conditions.

Of greater practical value is the type of dietary test advocated by Hedinger and Schliyer,<sup>2</sup> and subsequently developed with various modifications by European and American workers. Only one day is needed for the completion of the test, although in some clinics this is preceded by two or three days spent in getting the

patient on a constant water balance. The diet is standardized, but it is liberal, consisting only of articles usual on a mixed diet, including considerable amounts of meat, soup, tea and coffee. The essential feature of the test consists in determining the reaction of the kidneys to the diuretic substances contained in the latter articles. Specimens of urine are taken at regular times, which bear a definite relation to meals, and the volume, specific gravity, salt and nitrogen output are studied. The night urine is collected as a single specimen. Under normal conditions the variations in volume, concentration, salt and nitrogen excretion follow very definite curves. As the functional capacity of the kidneys becomes impaired, such changes are noted as the relative increase in the amount of night urine, lowering and fixation of the specific gravity, and decrease in the output of salt and nitrogen. The evidence which has so far been accumulated on this type of test indicates that these abnormalities of urinary excretion may occur quite early in the course of the disease,—even before the other tests show a decrease in renal function, and it seems probable that the use of this method may be of distinct service in the early diagnosis of chronic nephritis. The test involves, besides the administration of a simple standard diet, the accurate collection of specimens of urine, and chemical analyses which can be easily carried out in any laboratory. The interpretation of the results is not always simple, and as yet the number of published reports is scarcely sufficient to permit of broad generalizations as to its diagnostic and prognostic value, or its relative significance in comparison to other tests.

Another type of test for renal function consists in the comparison of the concentration of a given substance in the blood with the rate of its excretion in the urine. Ambard first showed that under normal conditions the rate of excretion of urea, or the amount excreted in a certain unit of time, depends on its concentration in the blood. The relation between the concentration in the blood and rate of excretion is known as the Ambard coefficient. In this country McLean,<sup>3</sup> at the Rockefeller Hospital, has devoted much attention to the development of the test. He expresses the relation of the rate of excretion of urea in the urine to the urea concentration in the blood by what he terms the Urea Index. Normally 100 or over, a drop in the Index signifies a lessening of the capacity of the kidneys to excrete urea. This method, which compares the amount of urea in the blood with that excreted in the urine in a unit of time is certainly much more reliable than are the methods which consist of blood analysis alone, for it has been shown that on the one hand high blood values may be associated with a normal rate of excretion, and on the other hand, normal blood values may be found when the Urea Index indicates a very low functional capacity of the

kidneys. Considered from a scientific point of view, the Urea Index probably gives the most reliable information concerning renal function. Its chief disadvantages, as far as they are known at present, are technical. In order that it shall be of any value, the Index must be based on extremely accurate chemical analyses of blood and urine. These can be carried out by well-trained technicians in hospitals and in private or commercial laboratories; but the sources of error are such as to put the test beyond the reach of the general practitioner.

The last type of renal function test to be considered is that which depends on the ability of the kidney to excrete some foreign substance. By far the most important method of this type is the now well-known phenolsulphonephthalein test of Rowntree and Geraghty.<sup>4</sup> This consists in the intramuscular injection of 1.0 cc. of a solution of the dye, and the determination of the percentage excreted in the urine during a period of two hours, by means of a simple, rapid colorimetric method. The test is so easy to perform that it can be used by any one, either in the office or the home, since no special technic is necessary, and no complicated apparatus is required. During the last few years the phthalein test has been tried out extensively in many clinics in this country and in Europe, and in general the results have proved extremely satisfactory. It has been shown by Thayer and Snowden<sup>5</sup> to give a satisfactory indication of the extent of the pathological lesion in the kidneys. Barring the conditions already discussed, in which any of the tests of renal function may fail to give satisfactory indices of the clinical condition, the phthalein test appears to be very reliable. Its value has recently received important confirmation in the comparative studies of McLean,<sup>6</sup> who has shown the phthalein output runs practically parallel to the Urea Index. The only serious divergence was found in patients with cardiac insufficiency, who were excreting very small amounts of water. These subjects excreted the phthalein more readily than they did the urea. The Urea Index is, moreover, according to McLean, a more delicate indicator in that it draws a somewhat sharper line of demarcation between normal and abnormal cases, while in the very severe cases, slight variations in the Index are of more significance than are corresponding variations in the phthalein output.

In reviewing the tests that have been advocated for the determination of the functional capacity of the kidneys from the point of view of the general practitioner of medicine, several criteria must be applied. In order that a test may be widely used it must not be time-consuming, it must not involve highly specialized technic or costly apparatus, and it must give sufficiently accurate information to warrant its application. The tests depending wholly or in part on blood analyses are too complicated to

come into general use outside of hospitals. The dietary tests require at least twenty-four hours and involve some chemical analyses, but they are quite within the field of most medical men. They are only very roughly quantitative, but they will probably prove to be of aid in the early diagnosis of renal lesions. Time and further experience will show whether they give information of value, which cannot be obtained in an even simpler manner. At present the phthalein test seems to stand out as being the most generally applicable of the methods. It has the disadvantage of depending on the excretion of a substance foreign to the body, but comparative studies have shown that the conditions governing its excretion are similar to those governing the excretion of urea. It is rapid; it is simple; it is, on the whole, very reliable. It is so easy a method of obtaining an accurate basis for prognosis in cases of nephritis, and it is so helpful as a guide to treatment, that it well merits the reputation it has achieved, and it should be even more widely applied than it has been hitherto.

## EYE CHANGES IN RENAL DISEASES—THEIR DIAGNOSTIC AND PROGNOSTIC VALUE.

By PETER HUNTER THOMPSON, M.D., BOSTON.

THE object of this brief paper is to bring to your attention the findings, diagnostic value, and prognostic value of the eyes in renal conditions.

During the years 1827 and 1836, Bright called attention to the impairment of vision experienced by certain patients having renal disease. Ever since that time the eye symptoms have attracted more and more interest. As none of the characteristic changes occurring in the eyes can be seen with the unaided eye, it remained until the invention of the ophthalmoscope, in the year 1851, before the intracocular changes could be seen and studied. After that, in course of time, the findings in the eyes became so well understood that they have, for many years, been of real value in making the diagnosis and a great aid in giving the prognosis.

All physicians may be aware of these facts, but many do not take advantage of the valuable information gained by an ophthalmoscopic examination. One familiar with the use of the ophthalmoscope can make such an examination quickly and safely, and with little or no inconvenience to the patient.

It is a very common experience of every ophthalmologist to find, while doing routine office or out-patient work, changes in the eyes of patients which soon lead to a correct nephritic diagnosis, many of whom simply come complaining of the ordinary symptoms of eye-strain, or, at most, blurring of the vision, all of which they expect to have corrected by proper glasses. When told of the real cause of their symptoms, and advised to consult their regular physician for examination and treatment, and his examination of the patient, together with the urinalysis, confirms the ophthalmologist's suspicion, it all seems quite wonderful to those not familiar with this possibility. This very likely accounts, by hearing of these cases through relatives and friends, for so many patients asking during or after an ophthalmoscopic examination, if any signs of kidney disease were discovered in their eyes.

While physicians may practically always be able to make a diagnosis of renal conditions from the symptoms and general examination of the patient, together with the urinalysis, without the necessity of making an ophthalmoscopic examination, they cannot begin to give the prognosis with the same degree of certainty which would be possible for them if they were also sure that the typical eye changes were present. Even though the examination of the fundi should prove to be negative in a case known to have nephritis, this fact is also very helpful in giving a more accurate prognosis.

The value of an examination of the eyes, in this connection, may be over-estimated by some, and under-estimated by others, but I hope to give you a sufficient number of facts recorded by different observers, and obtained by personal experience through private practice and my services at the Massachusetts Charitable Eye and Ear Infirmary and the Boston City Hospital, to enable you, as medical men, to judge for yourselves.

The clinical changes observed in the eyes are confined chiefly to the retina, optic nerve, and choroid. Retinitis, or the so-called albuminuric retinitis, shows itself by loss of transparency, white spots or patches, exudate, and hemorrhages in the retina, associated with certain changes in its blood-vessels, and rarely by separation of the retina itself.

Loss of transparency of the retina is frequently very evident. When viewing the fundus, the normal retina, being transparent, is not seen, excepting its blood-vessels, as we simply see the red reflex of the choroid showing through, but when it becomes inflamed, it sometimes takes on a more or less general cloudy appearance, resulting from infiltration and edema, obscuring, in proportion to its density, the normal red reflex beyond.

White spots or patches are the most characteristic and frequent changes observed in the retina. Wherever located, they render the

retina opaque at these points, presenting a very striking appearance as they are seen against the red background, grouped chiefly about the macula and optic disc. They vary much in size and shape, and often coalesce, particularly at the posterior portion of the fundus, and may even form, in this way, a complete opaque area surrounding the optic disc. We frequently see white glistening spots, drawn out into lines, radiating from the macula, but not involving it, arranged in the form of a star, and when present, they are very characteristic. This stellate figure is not always complete, being represented at times by only one, two, or three quadrants, or there may be simply an occasional white glistening dot in this vicinity.

Exudate is sometimes seen, but it varies greatly in appearance and amount in different cases and the various stages of the disease. It is usually more abundant in the neighborhood of the optic nerve, and frequently hides more or less completely the view of the retinal vessels and the outline of the disc. In many of the cases, there is no visible exudate.

Hemorrhages are usually present. They may be large or small, many or few in number. Sometimes they form lines along the course of the vessels, and occasionally they are represented only by mere dots. The hemorrhages may or may not have well defined borders and may be round or irregular, while others present a flame-like outline, depending upon the anatomical arrangement of the layer of the retina where the blood is confined.

Retinal vessels, the veins in particular, are usually more or less engorged and tortuous. The arteries generally show signs of arteriosclerosis. Thickening of their walls renders them less translucent, and sometimes they present a beaded appearance or have white lines or stripes along their course. Thickening of the walls of the arteries often compresses the veins when they happen to cross them, and thus impedes the venous flow.

Separation of the retina is quickly detected, when present, as the separated portion usually soon takes on a grayish appearance, hiding more or less completely, the normal red reflex. It projects forward, making it necessary to revolve a different lens before the sight-hole in the ophthalmoscope, in order to focus on its surface, so as to make it possible to see clearly the retinal vessels on the elevated area. This condition is quite often seen in the acute nephritis of pregnancy; otherwise it is rarely found.

The optic nerve usually shares sooner or later in the inflammation of the retina and occasionally shows the first signs of trouble in the eyes. The optic neuritis varies from a slight reddening of the optic disc, with some blurring of its borders, to marked swelling and exudate which completely obscures the outline of the disc, and it may even present the appearance of

choked disc. The usual picture observed in renal cases is a neuro-retinitis, both the retina and the optic nerve being involved, each sharing the same or one more than the other, in the inflammation.

The choroid is very likely more often involved, especially its blood-vessels, than we are able to make out with the ophthalmoscope, but we do see cases having well marked patches of choroiditis associated with the retinitis. The choroidal patches may finally become white centrally, from destruction of the choroid at this point, showing the white sclera, having dark pigmented borders, but they are readily distinguished from the white opaque patches due to the retinitis.

Associated with these changes, there is, sooner or later, impairment of vision. The amount of visual disturbance depends chiefly on the part of the eye involved. Slight changes in the macular region, or center of acute vision, will reduce the sight more than extensive changes in other parts of the fundus. On the other hand, cases showing quite extensive changes, away from the macular region, may retain good central vision for several months before it is finally reduced by involvement of this area.

While we do get other changes in the eyes in renal affections, those mentioned are the ones we rely on chiefly in making the diagnosis and, in nearly every case, it will be found to be correct. There is a great variation in these findings in different cases, and in the various stages of the same case. In some, the white spots or patches of the retina will be the prominent feature, in others, the retinal hemorrhages, and in others the optic neuritis. Both eyes are usually affected sooner or later, but the relative amount of involvement of each may vary greatly at different times.

Many of these renal cases present a picture so strikingly characteristic, when viewing the fundus, that the examiner is able, with but few exceptions, to make the diagnosis from this alone; but syphilis, brain tumor, certain forms of anemia and diabetes, especially the latter, occasionally show similar changes in the fundi, therefore it is wise also to have a careful examination of the urine in every case. However, when seeing such a picture we know at once that if it is not caused by nephritis it is due to some other equally serious disease. Even when the changes in the eyes are very slight, and not especially typical either, they often lead to a correct diagnosis by the ophthalmologist suggesting other examinations, with the view of finding the cause of the local disturbance.

The percentage of all renal cases, showing changes in the eyes, seems to vary considerably as given by different observers. Perhaps about twenty-five per cent. would be a fair average. Quite a number of people have the impression that every case of kidney disease will show signs of its presence in the eyes. Of course this

is not so. No doubt there are minute changes, particularly in the blood-vessels, long before they become sufficiently well marked, so as to enable us to distinguish them with the aid of the ophthalmoscope.

However valuable the findings in the eyes may be in making the diagnosis, it is the reference to the prognosis regarding the duration of life of patients having renal disease, in whom we also find characteristic changes in the eyes, that is of special importance, as it can be given with a far greater degree of accuracy than by the results of all other examinations combined. In making such a diagnosis, you are, in reality, rendering a death sentence upon the individual, which will probably take place within two years, even in those who are apparently enjoying good health at the time, and able to attend to their usual occupation. The duration of life, after the eyes become involved, is shorter in the poorer classes and longer in the better classes. It is usually longer in women and shorter in men in all classes. The prognosis is much more unfavorable when associated with chronic nephritis, than with the acute disease. The outlook is quite favorable, both in regard to life and vision in the acute form when the renal disturbance is entirely due to scarlet fever or pregnancy, especially in the latter, but if separation of the retina takes place, the vision may remain poor in the eye thus affected. Patients in whom we find an albuminuric retinitis, associated with chronic kidney disease, usually die within one or two years; rarely do they live longer than three, more often it is less than one year. Life has been prolonged occasionally for longer periods, when such patients have been able to provide favorable hygienic surroundings combined with proper diet and careful treatment. Under such conditions, the time has varied in exceptional cases, even up to twelve years.

A good deal has been said and written regarding the duration of life after the eyes become involved in these renal cases, by different writers and observers, and their figures and impressions naturally vary considerably because their work has brought them in contact with different classes of patients. Some have gathered their figures from private patients alone, others from hospital cases altogether, and others from hospital and private cases combined. Out of 155 private cases reported by Belts, 62% of them died inside of a year, 85% within two years, 14% lived longer, while out of 175 hospital cases, 85% died inside of a year, 93% died within two years, 6% lived longer. Bull reported 103 cases and 87% of these died within two years. Out of a series of 100 cases collected by Bell, from the private practice of different men, 73% died within one year, and 94% within two years. In a collection of 419 reported cases, Rogers found that 90% of them died inside of two years. Several other series of cases, some larger and some smaller, have

been reported by different men, but those given will serve to illustrate sufficiently the great aid in giving the prognosis in renal cases, regarding the duration of life, furnished by the additional knowledge of the presence of characteristic changes in the eyes, especially when we realize how uncertain it is in such cases when the eyes do not present these changes.

#### DISCUSSION.

DR. CHANNING FROTHINGHAM, JR., Boston: Mr. Chairman and members of the Society: After listening to these two very interesting papers, it is hard to do anything more than to simply reiterate what has already been so completely expressed.

There is one point on which I feel that I should like to criticize Dr. Peabody's paper. I fear, however, that probably none of you will agree with me. I think we ought to stop using the term, "chronic interstitial nephritis." It seems to me it is a rather vague term, although well grounded in the minds of the profession. If one looks at Dr. Mallory's excellent book on pathology, and sees how he has gone back to the original lesion in his classification of chronic kidney disease, it seems only reasonable to adopt his nomenclature, so that from the name, one may draw a mental picture of the disease from the outset. Chronic vascular nephritis is the name which should be applied to most of the cases of interstitial nephritis. At the present time, however, it is impossible by our methods of diagnosis to tell the difference between chronic vascular nephritis and the late stages of a chronic glomerulo-nephritis, although under the microscope the difference is readily seen.

Before emphasizing the points which Dr. Peabody has mentioned so well, I think the first thing for the practitioner of medicine to realize is that it is practically impossible with the means which we commonly use for making a diagnosis of nephritis to make an accurate prognosis. In other words, the examination of the urine for albumin and casts and estimation of the blood pressure only help us in making a diagnosis. The amount of albumin and casts in the urine is simply indicative of the amount of kidney destruction which is going on at that time. They are not indicative of how long that particular kidney is going to last. An increased blood pressure is probably indicative of a chronic nephritis. It is not indicative of the severity of the nephritis. Frequently we see cases as they reach their terminal stages and are becoming uræmic with the blood pressure considerably less than people who are apparently well and active.

The examination of the eye grounds may be of some prognostic as well as diagnostic value. For, although evidence of nephritis, when found in examination of the eye-grounds, as Dr. Thompson has pointed out, is a bad prognostic

sign, you must remember that a good many cases come to a fatal termination without evidence of changes in the eye-grounds, at least so far as they may be detected by those who are not expert in an examination of the fundi. Therefore, after making the diagnosis of nephritis, you either have to guess as to the length of life of the individual patient, or else you have to turn for aid to some of these functional tests which have been presented. Of the functional tests, I agree with Dr. Peabody, that the phthalein test at the present time is probably the most satisfactory for the general practitioner.

Let us remember that in the early stages of chronic nephritis, practically all of these renal function tests may be normal, and, therefore, that they are only of prognostic value as the nephritis becomes more advanced. In certain cases of nephritis, the phthalein test may be normal, and in certain cases of passive congestion without renal involvement it may be abnormal. It is, therefore, advisable to do more than one test for renal function, if possible, in each case. The other test which seems to me to be practical for the practitioner to make, is the examination of the blood for urea or total nitrogen. I do not mean that the practitioner will have to make the chemical analysis himself, but that he should simply draw the blood under the conditions which are recommended in these tests, and then send it to some laboratory equipped for making such examinations. In a given case of chronic nephritis, therefore, after making the diagnosis, you should turn to the functional tests. First estimate the ability of the kidney to eliminate phthalein. If that is normal, it is usually safe to assume that the nephritis is not far advanced, and further studies are not so necessary. If that is abnormal, however, before a definite prognosis is made, other tests should be done. Either the general practitioner can collect the blood and send it to a laboratory for a study of the urea or nitrogen, or he may avail himself of one of the various clinics which are now springing up throughout the country at which, in a few days, careful studies of the renal function may be made. This in no way should interfere with the relation between the practitioner and his patient, for it is understood that such patients are going to the hospital only for functional studies, and not for treatment.

There is one other point that might be mentioned here. All of our functional tests, or at least the great majority of them, at the present time, simply tell us how sick a nephritis case is. We hope, then, in the future, that functional or other tests will be devised which may be applied to mild cases of nephritis or to incipient cases, so that we may make an earlier diagnosis and institute more intelligent treatment in time to vary materially the course of the disease.

DR. GEORGE S. DERBY, BOSTON: Mr. Chairman and gentlemen: Dr. Thompson has covered this subject of the eye changes in nephritis so well, that all I can do is to add, perhaps, one or two points which, on account of lack of time, he was unable to put in. The first thing I want to call your attention to is the fact that albuminuric retinitis is not the only process which occurs in renal disease. We have also the so-called uraemic amaurosis, which is an entirely different proposition, due to uraemic poisoning, and which comes on as sudden blindness in from eight to twenty-four hours in the patient, accompanied by the other signs of uremia and often coma. This clears up in from twelve to twenty-four hours, the vision comes back to normal, and an examination during the time of blindness discloses absolutely nothing in the fundus whatever, because the process is situated back in the brain.

Now, the term albuminuric retinitis is a misnomer. It should be called renal or nephritic retinitis, because the albuminuria has nothing at all to do with it.

As Dr. Thompson said, twenty-five per cent. would be a fair estimate of the proportionate number of cases in which it occurs. Some estimates run below that. Probably if cases of this nature were followed until death occurred, we should find it in about one-third, thirty-three per cent. In the nephritis of pregnancy, it is rather less common.

Now, I feel that I differ a little bit from Dr. Thompson in what he said about recognizing these cases of albuminuric retinitis. It seems to me that the cases where you can say right out, "This is surely a case of renal disease," are in the minority. There are a great many cases where the appearance suggests it, but where it is not absolutely typical and you can only surmise it. In addition to that, there are a great many cases where the changes are extremely slight and you must have your other examinations made before you can say that the changes are due to a nephritis.

In a paper by Dr. Sloeum, of Ann Arbor, Michigan, which is going to be presented a week from today at Detroit, out of seventy-three cases of nephritis where the eyes were examined very carefully, only five were found in which the typical star figure of albuminuric retinitis was present—only five out of seventy-three, that is, about six per cent.

It is in the cases of interstitial nephritis where the diagnosis is more often made by the oculist first. The patient suddenly notices a blurring of vision, goes to the oculist, and a well developed retinitis is seen. I remember seeing such a case when I first started in practice. The patient, who was under treatment by a very good general practitioner for indefinite gastric symptoms, had not had her urine examined. She showed a well developed nephritic retinitis and was dead in two weeks' time.

Now, in all probability, according to the best opinion of the present day, the renal retinitis develops only if the disturbance in renal function has given rise to considerable changes in the arterial system, increased blood pressure and usually hypertrophy of the left ventricle. The disease is very rare under twelve, is common between thirty to sixty, most often seen between fifty to sixty; and except in the pregnancy cases it is seen very much more often in men. You see two cases in men to one in women. In a great majority of cases the disease appears in both eyes with a very short interval between, a few days or weeks. There are, however, some cases on record where the disease has remained entirely monocular, confined to one eye up to the time of death.

There are also changes appearing in the eyeground which cannot be classed as retinitis, and which appear much earlier in the disease. I refer to the vascular changes which are seen in the eyeground and which usually mean that there is a cardio-renal lesion. I think that in the recognition of these lesions the ophthalmologist can be of great use to the general practitioner. One needs a considerable amount of skill and perseverance to discover these lesions, and a certain amount of experience is absolutely necessary,—the sort of experience that one gets from the examination of cases in the general hospital, such as Dr. Thompson has in his examinations in the wards of the Boston City Hospital. For instance, I see a great many cases each year at the Massachusetts General Hospital where there are these slight changes, and those cases mostly are of cardio-renal disease,—cases where the prognosis is not so absolutely unfavorable as in those instances where you find a very definite retinitis. I think the ophthalmologist can do a great deal in the routine fundus examination of people as they come for glasses between the ages of forty and sixty, and can very often spot a lesion in the vessels and send the patient around to the general practitioner. Very often in that way quite a number of useful years can be added to the patient's life, by discovering the lesion earlier than it would be discovered otherwise.

#### REMARKS ON BLOOD-PRESSURE.

DR. G. V. N. DEARBORN, Cambridge: Mr. Chairman, and ladies and gentlemen: In the course of uncompleted observations on the relations of the mental process to blood-pressure (which has been my chief and particular form of research for two or three years), I came to a knowledge of the extremely wide variations in the blood-pressure,—both diastolic and systolic, and in both children and adults,—which I am sure is of practical application and of practical use to the average clinician. I have here about 140 graphs made from relatively continuous records of blood-pressure, each from two minutes up to about one hundred minutes in length

(one hour and three-quarters)—something, I think, which has not been done before. These are the originals, and I pass them around, for I would like to have you see what they are like; I am sorry that I cannot circulate them in some sort of regularity, or in order.

The best I can do, of course, in my brief allowance of time, is to suggest very summarily indeed some of the clinical conclusions which I think would be of the most practical interest to you. The first thing I want to point out is that there are always at least six or seven uncertainties in every blood-pressure determination. The first one (most commonly overlooked) is the *muscular tension of the arm*. The arm, of course, is actually not a fluid. Theoretically for blood-pressure tests it is a "perfect fluid," but in reality it is not so, and any increase in the tonus of the muscles certainly changes the blood-pressure. The second uncertainty is the *varying tension of the artery*, an element which has been sometimes overlooked. The artery, in order to be relatively incompressible, does not have to be sclerosed; it may be merely vasoconstricted. Of course you have a continually decreasing resistance to your decompression as the artery becomes less and less constricted. Third, is the *shape of a cross-section of the artery*. When it is a round tube it is obviously a series of arches, but as the artery collapses these become broken arches, and of course these are very weak as structural units. The fourth element that is to be taken into consideration is the *training-index* of the patient, whether the patient be a physically trained individual or not, and particularly whether he has had very recent exercise or not. A physician recently told me about a layman who went up in a high office building in New York City to have his blood-pressure measured and to take the remainder of a life-insurance examination. The elevator was not running and he walked up four or five flights of stairs in a hurry and excitedly. On the basis of his blood-pressure he was "rejected." The *excitement-index* of the patient necessarily comes into all these cases and is an important unknown factor until determined. The *mental activity* of the patient is a factor,—whether he is emotional or not, whether he is thinking or not, and so on. Then, occasionally I have found in the 4,800 measurements of blood-pressure which I have made in the last three years a distinct *dilatator spasm* (or *else atony*) of the artery, something which, so far as I know, has not been described, but which immediately "throws out," i.e., stops, all of the Korotkoff sounds which you have to hear in determining the arterial tension. The artery certainly "has a habit" under conditions to be determined, of suddenly expanding, and thus losing all the sounds. There is finally a *vasomotor neurosis*, not the "hypertonia vasorum idiopathica" that you find described in some of the text-books, but a distinct neurosis of

the immediate vasomotor apparatus which gives rise to long-continued high blood-pressures. For instance, a worried man of sixty-five had his pressure consistently up to 260 two or three years ago; he had no discoverable lesions in the kidneys or in any other organs whatever; he is now down to a reasonable blood-pressure for that age. I think we must be expecting soon the neurologic description of a vasomotor neurosis, one might almost call it a psychosis, which raises blood-pressure far above the danger sign, for example, in interstitial nephritis.

Now, there are certain practical and clinical deductions which I venture to make from these 140 "continuous" graphs which are in your hands. I have divided them into nine groups, and when the research-report is properly prepared they probably will be set forth in that manner. In Group A, there are those curves which show an enormous initial variation from day to day, sometimes as much as thirty millimeters with no apparent cause whatever except recrudite physiological conditions, which seldom have been taken into consideration. Group B shows a large and progressive fall from the first taking for 15 or 20 minutes. The average physician over the land does not realize, when he finds a patient's pressure a little higher than he thinks it ought to be, that perhaps 20 minutes later it may be 30 or 40 millimeters lower. One of these graphs shows 34 millimeters progressive physiological fall within 15 minutes in a normal individual under the quietest conditions.

Voluntary relaxation plotted in Group E is something I wish to call to your attention simply as a matter of expediency in insurance-examinations. A physician in a neighboring town voluntarily relaxed his muscles and in that way, as you see, reduced his blood-pressure, and then raised it by holding his breath, so that there was within 15 minutes a voluntary rise of 119 millimeters. First, he deliberately lowered his pressure (systolic) about 24 millimeters, and then he raised it to 230, a voluntary variation of 119 millimeters within 15 minutes, down and up. Anyone that understood the trick could do that in the course of a life-insurance examination, and no one the wiser, under present methods of using the gauge.

Normal variation is enormously large, as Group F shows. The most marked graph which I have had showed a wholly spontaneous variation up and down of approximately 40 millimeters within five minutes. This was a woman of about fifty-nine, a normal person, but a nervous woman with "a New England conscience," as Professor Putnam says, a woman whose autonomy is undoubtedly easily affected by emotional and intellectual stimuli.

Anesthetics (Group J) have characteristic blood-pressures. Mental defectives (Group H), the so-called feeble-minded, also have charac-

teristic blood-pressures, into the nature of which we cannot now go.

I wish to suggest that the diastolic pressure is only a little less variable than the systolic. One medical gentleman, again, said, "We never pay much attention to the blood-pressure of children anyhow." But my records, graphs, show that blood-pressure is almost as variable in adults as it is in children, and often more so.

I wish, then, to suggest as theoretic corollaries, that in the first place the physiologists should study vasomotion, and study it extensively. We must investigate the physics of the arm. We must understand the mental influences.

And then there are five practical corollaries: In the first place, *use twenty minutes instead of one in "taking a blood pressure,"* both diastolic and systolic; use twenty minutes instead of one, and take both the readings every minute, or at least every two minutes. I see one clinician smiling at that, but it is either that, ladies and gentlemen, or else a doubtful report; either fifteen or twenty minutes, or a misleading notion of that individual's real, effective blood-pressure. Second, *interpret no reading, save as the algebraic balance of two dozen or more factors and modifiers.* Third, *don't scare the patients,* unless you have some personal reason for taking too high a blood-pressure. Fourth, *the pressure in the brain and in the autonomic centers is more important than the pressure in the arm;* and we need a method of finding the pressure in these former places. And, fifth, there is probably a frequent neurosis, a well-defined "middle-age" vasomotor neurosis, which raises the blood-pressure without indicating anything of broad prognostic significance so far as we at present know.

DR. H. D. ARNOLD, Boston: The papers have been presented so ably that there is little room for discussion. I would like to say just a word, however, in reply to Dr. Frothingham's challenge,—that probably the rest of us wouldn't agree with him in abandoning the use of the term, "chronic interstitial nephritis."

It seems to me that perhaps it is better to "bear those ills we have than fly to others that we know not of," particularly as one of the really disappointing conditions in our present study of nephritis is the failure of the pathologist to correlate the pathological evidence with our clinical experience. Dr. Frothingham's suggestion of "chronic vascular nephritis" in place of "chronic interstitial nephritis" is valuable, I believe, for a considerable number of cases; but until we know the subject a little more thoroughly and know how far that term, "chronic vascular nephritis," would be a really proper term for our cases, I believe we should be no better off than we are with the present term,—recognizing that the present term is unsatisfactory.

A very interesting thing to me in studying

the cases clinically, which are ordinarily classed under the head of chronic interstitial nephritis, is to find a class of cases in which regulation of the diet seems to be followed by a very definite reduction in the blood-pressure. In these cases the natural interpretation seems to be that when you get the demand for elimination down to the capacity of the kidneys you have relieved a condition which is a factor in the high pressure.

Now, there is a class of cases in which the blood-pressure is only slightly, if at all, affected by dietary treatment; and it seems to me that in those cases at least the high pressure is very likely a compensatory measure. In some of these cases which I have studied by the functional tests, it has been shown that the vascular system is much more concerned in the process than are the renal elements proper. I believe we are going to recognize clinically, as we go on, different sub-divisions of what we now call chronic interstitial nephritis, and that one of these sub-divisions will be these cases where hypersensitiveness of the vascular system is a determining factor. I am wondering whether "chronic vascular nephritis" is not a term to be reserved for this sub-division, rather than to be applied to all cases which we now class as chronic interstitial nephritis.

#### THE PHYSIOLOGICAL POINT OF VIEW AND AUTOPSIES.

By FRANCIS H. McCrudden, M.D., BOSTON.

Laboratory Director, Robert B. Brigham Hospital.

THE usefulness of a point of view once established, the problem arises of extending its influence. At the Robert B. Brigham Hospital where we are demonstrating to physicians,<sup>1</sup> students,<sup>2</sup> patients, and others, the usefulness of the physiological point of view of the problem of treatment in chronic disease, it is evident that the patients appreciate its usefulness.<sup>3</sup>

From the large proportion of cases of death in which permission for autopsy is obtained, it has become evident that our ideas are spreading to the relatives of the patients.

Since the hospital opened on April 1, 1916, complete autopsies have been carried out on 70% of all those dying (35 autopsies in 50 deaths). The figure for 1914 is 74% (14 cases out of 19 deaths); that for 1916 so far (May 1) 100%. No other American hospital has attained results that at all approach these.

The figures which follow, taken from a report

in *The Modern Hospital*,\* show the best results in other American hospitals:

	PER CENT.
Robert Breck Brigham Hospital, Boston.....	70.0
Peter Bent Brigham Hospital, Boston.....	58.5
University of California Hospital, San Francisco	56.8
Presbyterian Hospital, New York.....	24.8
New York Hospital, New York.....	20.6
Boston City Hospital, Boston.....	14.7
St. Luke's Hospital, New York.....	14.4
Bellevue Hospital, New York.....	11.8
Mount Sinai Hospital, New York.....	7.3

(During one year Johns Hopkins Hospital performed autopsies in 62.5 per cent. of the deaths.)

An examination of the reasons for the difference in the figures would show, of course, that many factors are involved; but in the last analysis success depends on the degree to which the relatives can be made to appreciate what has been done to help the deceased, and the extent to which they can be made to understand that in giving permission for a post-mortem examination they may be contributing something toward helping other patients; the extent, in other words, to which they catch the hopeful spirit of our physiological point of view.

The figures bring out one other point, namely, that the emphasis laid on the physiological point of view need not lead to any neglect of pathological anatomy; in our hospital the direct result has been, on the contrary, an increase in the possibilities for pathological-anatomical studies.

#### CORSETS VERSUS BACKACHE AND FATIGUE.

By ALICE S. CUTLER, M.D., WESTBOROUGH, MASS.  
*Westborough State Hospital, Westborough, Mass.*

THE subject of corsets may not be an interesting one; but to me, as a woman physician (being on the staff of one of the large state hospitals) who has examined over a thousand women vaginally during the last five years, it has been instructive in showing me that the majority of women suffer from the ill effects of bad corseting.

I heartily agree with Dr. Robert L. Dickinson

\* Antepos Increased in Number, *The Modern Hospital*, p. 187, March, 1916.

of New York, who has made the following statement: "Many feminine ills are due to incorrect corseting and defective corsets."

For two years I have been experimenting with corsets, on patients, nurses, and my home friends. The idea was put into my head from pelvic conditions found in a physician's wife, who suffered from severe backaches and fatigue. (She had been advised by a number of physicians to have a ventral fixation.) A vaginal examination showed a retroversion of the uterus which was freely movable. While she was dressing, I observed the way she put on her corsets, and asked her to lie down on the examination table with them on—where before the uterus was freely movable, this time I could not lift it up without causing her great pain and discomfort. I advised her to buy a pair of front-laced corsets, which she did the next day. I showed her how to put them on lying down (with a pillow placed under the buttocks). I examined her again with these corsets on and found no displacement. She has made the statement a number of times that she never felt better; has no backaches, nor does she suffer with fatigue when she has to be on her feet a great deal. She plays tennis, dances, and does everything that a normal, healthy woman ought to be able to do, but cannot.

After my experience with the physician's wife I began working with women patients, nurses and employees. In over four hundred women, I found a backward displacement caused by the ordinary back-laced corset, put on incorrectly as most women fasten them together. With the nurses and employees who have changed from the back to the front-laced corset, there is complete satisfaction; they have all told me that at the end of their day's work they felt fresh enough to dance all night.

I know from my own personal experience that, since I began to wear front-laced corsets, I feel like a different person; where, a number of years ago, I was easily exhausted after working a few hours, now I do not know what fatigue is.

To cite a few cases:

CASE 1. Two young women in my home town (ages eighteen and twenty-one) thought they had to give up playing tennis, thinking the exercise too strenuous, because they suffered from severe backaches and pain in the lower part of the abdomen after this exercise. When they were fitted to front-laced corsets they both became enthusiastic, for they felt they could run all day without a symptom of a backache or abdominal pain.

CASE 2. Last summer one of our nurses wanted to enter a dancing contest, but was afraid she could not stand the physical strain, knowing that she easily "lost her wind." Front-laced corsets gave her confidence and allowed her to breathe in a normal manner. She and her partner won a prize.

CASE 3. A large, obese woman of fifty, with pendulous abdomen and breasts, while walking from

the gate to the main building (up a slight incline, a distance of two hundred feet) became dizzy. She came into the office and made the following statement to me, "I feel that something serious is going to happen." We went into the examining room. I took her systolic blood pressure and found it to be 186. Her face was scarlet, her feet and hands cold and clammy, heart action rapid and tumultuous. I helped her to undress; instead of unhooking the corset I cut the laces (in the back). The way the corsets were put on showed why she had marked dyspnea. I felt that her whole trouble was due to the corsets, and told her to buy a pair of front-laced corsets. In her case I had her put them on lying down, with hips elevated. This woman has been made so comfortable by being able to breathe and by not becoming dizzy when she walks, that she feels I have done her a great favor by demonstrating that the trouble was due to her corsets. Her blood pressure at the present time is 155.

I could cite cases indefinitely of the new lease of life given to women by wearing a properly fitted front-laced corset. I really hope this article will be the means of stirring up the medical profession to question their women patients about corsets; for women have made the complaint to me that their family doctors never ask them what kind of corsets they wear, and they are also surprised that corsets make such a difference in their own personal health.

### Society Reports.

#### CLINICAL CONFERENCE OF THE NEUROLOGICAL INSTITUTE, NEW YORK.

REGULAR MEETING, MARCH 14, 1916.

J. RAMSAY HUNT, M.D., in the Chair.

##### MYASTHENIA GRAVIS IN A CHILD OF EIGHT YEARS.

DR. J. W. STEPHENSON presented from the Second Division a girl 8 years of age, Hebrew. She is the youngest of three children, the others being in good health. It is said that her father's blood serum showed a four plus Wassermann. She was healthy until she was 9 months old, when she was vaccinated. Following this she is said to have developed blood poisoning. Her arm was swollen, she had a high fever, etc. Soon thereafter her mother noticed that the eyelids would occasionally droop, and then as the child began to walk it was noticed that she would tire easily. These two symptoms have persisted with remissions and are the two symptoms for which relief is sought. The mother's story is that the child wakes in the morning with eyes wide open, but after she has been about for two or three hours, the eyelids begin to droop and she complains of tiring, in fact has to sit down in order to become rested. She cannot walk more than three or four blocks without tiring.

Examination revealed a well-nourished girl, showing a double ptosis. There were no marks of degeneracy, no atrophies, no sensory disturbances. No evidence of persistent thymus. Blood pressure, 90. Pupillary reaction normal. Eye mobility in all directions upon first examination showed a decided

weakness, and upon repeated examination the patient was unable to perform any movements of the external muscles of the eyes. In other words, she showed a complete ophthalmoplegia externa. The child was allowed to rest in a recumbent posture, eyes closed, for a half hour, after which the ptosis disappeared, and eye movements, though not making a complete excursion, showed a definite amount of power. After putting the child through various tests for about five minutes, the phenomena mentioned above reappeared. There was no involvement of the muscles of deglutition or mastication. The knee jerks were lively, but upon frequent percussion became less active, but never entirely disappeared. The plantar responses were flexor and there was no alteration of the abdominal reflexes. Serological investigations of blood and spinal fluid were negative. The electrical reactions by Dr. Rochfort were as follows:

"The response of all the facial muscles is considerably reduced to faradism, particularly in the orbicularis oculi and occipito-frontalis. When these muscles are repeatedly stimulated, three times per second, the muscles soon show sign of fatigue. The response gradually becomes slower and less forcible, and finally after about 80-90 contractions disappear in the occipital portion. After a rest of two seconds the contraction is again about as vigorous as at the beginning. This phenomenon is doubtless a typical myasthenic reaction."

In concluding the presentation, Dr. Stephenson stated that the ophthalmoplegia externa with ptosis could be explained by the existence of poliomyelitis superior, bilateral disease of the quadrigeminal bodies, or myasthenia gravis; but the variable course of the disease, and the definite myasthenic reaction, proved conclusively that the patient was suffering from myasthenia gravis, the interesting features being age of onset, viz: first year of life; the four plus Wassermann in the father, and the fact that the condition followed a severe infection. The latter two conditions he considered, if followed up, might throw some light on the etiology of the disease, which as yet has to be fully explained. He also stated that, to his knowledge, the patient was the youngest case of myasthenia gravis on record.

##### A CASE OF BRACHIAL PLEXUS PARALYSIS.

DR. EDWIN G. ZABRISKIE presented from the First Division a girl of 17 years, single; occupation, a demonstrator of sheet music. Her family history is negative; both parents are living and well. She has two brothers and two sisters, all living and well. As far as can be determined, her infancy and her early childhood up to her seventh year were uneventful. At the age of seven she had an attack, which was characterized by swelling and pain in the arms and legs. She is uncertain whether it was confined to the joints or to the muscles. She was laid up in bed six weeks. She made, however, an uneventful recovery, but about six months later her left hand began to shake in the manner of a fine rhythmic tremor, which was somewhat increased by emotion. While rubbing the hand with a lotion, her mother noticed that the outer surface of the dorsum of the left hand was becoming thinner, and she says there was a marked tenderness and some pain along the last two interossei. About the same time she noticed that she was losing the power to extend fully the little and ring fingers of this hand, and that they were becoming slightly bent. After

a few months the pain and tenderness ceased, but she never regained the power to stretch out those two fingers, and the flattening of the hand at that point always persisted. She was always able to straighten them by using her other hand, and this process never caused any pain in the palm. When she was 13 years old she was shot in the right eye, and as a result of this she lost the sight completely in that eye; the right globe has also become fixed, and coincidentally she developed a paralysis of the left external rectus, which has also persisted. She at the age of 12 began to study music, and until a short time ago has been able to earn her own living at this occupation. About 1½ years ago, from no cause that can be ascertained, she developed pain in the left hand extending up the arm as far as the shoulder, which she described as a dull tearing pain something like a toothache. At the same time she began to notice a further atrophy of the entire hand, and it has gradually become weaker, more powerless, until at present she is unable to use it for anything requiring the least amount of power; for instance, she is unable to steady her meat with a fork, while she cuts it.

*Status præstans.* Delicately built young woman, whose physical state, except for the condition of her eyes and left arm, is normal. There is double abducens paralysis and right phthisis bulbi. The entire left arm is much smaller than the right and averages 3.5% less in circumference. The greatest amount of atrophy is in the thenar, hypothenar and interosseous muscles. All movements of the arm and forearm are possible, but the gross muscular power is greatly reduced. Flexion, extension, adduction and abduction of the hand are reduced to a minimum, and she is unable to perform these motions against the least resistance. Movements of the fingers are restricted to slight flexion of the thumb by means of the flexor longus pollicis; extension of the thumb by means of the long extensor. Flexion and extension of the little and ring fingers, adduction and abduction of all the fingers are abolished. Sensation is normal in the upper arm and radial distribution of the forearm and hand. The cutaneous distribution of the ulnar nerve shows a distinct hypæsthesia for all forms of sensation. For a distance of about 1½ inches above the wrist it is well marked, but above this joint it diminishes in intensity until it is quite indefinite at the elbow. The electrical responses are diminished but there is no qualitative alteration.

Radiograph of the neck reveals no abnormality of the bony structures, but on palpation, a small rounded mass can be felt just beneath the lower insertion of the left sternocleidomastoid. Pressure on this mass causes a shock-like pain referred to the inner aspect of the forearm and the little and ring fingers. Unfortunately, exploratory operation was refused, and it became, therefore, impossible to demonstrate this mass as the pathogenic factor.

#### PARALYSIS AGITANS WITHOUT RIGIDITY.

DR. J. RAMSAY HUNT presented from the Third Division a case of generalized tremor of the Paralysis Agitans type, unassociated with the muscular rigidity which usually accompanies this disease.

The patient was a man thirty years of age, of Irish extraction, a laborer by occupation. He was admitted to the Neurological Institute on February 1, 1916, and gave the following history.

There is no familial tendency to tremor or other nervous disease. He is moderate in the use of alcohol and tobacco. Eight years ago he acquired syphilis and received three years' continuous treatment with mercury by hypodermic injection, potassium iodide, and five full intravenous injections of salvarsan at intervals of three weeks. He states that coincident with the chancre there was a moderate jaundice, which was transitory in character. He has had no shock or injuries, and is unable to assign any cause for the tremor, which first made its appearance three and a half years ago in the right hand. It gradually progressed, involving the entire right upper extremity, and two years later appeared in the lower extremities. During the past year, when the tremor is severe there is also a difficulty in articulation. The left arm is also slightly involved, but in a much less degree. The tremor is slow, coarse and rhythmical, ranging from four to five vibrations a second. It is very much exaggerated by mental excitement and by observation. He states that on awakening in the morning he is comparatively free, at times totally free, from tremor. It makes its appearance after he is up two or three hours and lasts during the day, usually progressing as the day goes on. It is very coarse and violent when under excitement and if he tries to control it. While taking his history, he will often rise and pace up and down, and this relieves somewhat the tremor paroxysms. The tremor movement diminishes or ceases on intention, and he is able to lift a glass of water to the lips without spilling, and shaves himself every morning without difficulty, using an ordinary razor. It has also diminished and is very much ameliorated by the use of hyoscine. Since the onset of the tremor there is a marked tendency to hyperidrosis. He perspires very freely, and this manifestation is generalized, and not confined to any one extremity. There are no pains, no paraesthesias, and during his sleep all movements cease. The tremor is not relieved by taking alcohol.

A careful neurological examination reveals the following symptoms: There is infrequent winking, this reflex taking place only at long intervals of one, two and three minutes. The posture, manner of holding the arms and hands, the expression of the face, are very suggestive of Parkinson's disease. There is no well-defined Parkinsonian mask, but the face lacks a certain mobility of expression. The positions of the tremulous hands, however, especially the right, are quite typical. In walking, he holds the right arm stiffly and to a lesser extent the

James F. Innegan

left, and they do not partake in the natural associated movements which accompany this act. There is absolutely no rigidity of the muscles. The (cog-wheel) symptom, on making passive movements of the upper extremities, is suggested, but not characteristic of the Parkinson's disease. While there is no hypertonicity of the muscles, on the other hand there is no hypotonia, and the bodies of the muscles stand out quite firmly under the skin. There is no loss of power. The tendon reflexes of both the upper and lower extremities are normal and equal on the two sides. The pupils are equal and react to light and accommodation, and the cranial nerves are negative. The outline of the optic discs is clear and there is no evidence of neuritis. All of the skin reflexes, including the plantar, cremasteric, abdominal and sympathetic reflexes are present and normal. There is no disturbance of the objective sensibility. The visceral examination is negative, save for a left inguinal hernia. The speech shows a slightly tremulous character but is otherwise normal. Special senses are undisturbed. The urine is negative and the Wassermann examination of the blood and cerebrospinal fluid is also negative. There is no pleocytosis.

*Remarks.*—The case is regarded as an example of paralysis agitans without rigidity. This tremor form of Parkinson's disease is quite rare, and is by no means as common as the other incomplete type, namely, paralysis agitans without tremor. The diagnosis is based on the paralysis agitans type of the tremor; its cessation during rest, occurrence during activity; the synchronous, vibratory character of the tremor, which has the same rhythm in all the extremities. It can be inhibited by the will, but reappears in other parts of the body during the act of inhibition. Other additional signs indicating a Parkinson's disease are: the infrequent winking, the posture of the hands, the expression of the face, and the absence of associated movements of the arms in walking. It was thought that an *essential tremor* could be excluded because of the absence of the familial history, the unilateral onset in the right upper extremity and the Parkinsonian characteristics of the movements. The *chronic progressive cerebellar tremor* was also excluded because of the absence of any increase of the tremor movement on intention, as well as the absence of cerebellar elements, such as dysmetria, dysynergia, intermittent asthenia, and hypotonia which are associated with this disease.

Paralysis agitans may occur as a presenile or juvenile affection, and in a symptomatic form. It may appear without tremor (paralysis agitans *sine agitatione*), and, as in this case, it may appear without rigidity, this latter form being by far the rarest type of the affection. Similar cases have been described by Kurt Mendel, Oppenheim, and O. Foerster.

---

### Book Review.

*Practical Physiological Chemistry.* A Book Designed for Use in Courses in Practical Physiological Chemistry in Schools of Medicine and of Science. By PHILIP B. HAWK, M.S., Ph.D.

Professor of Physiological Chemistry and Toxicology in the Jefferson Medical College of Philadelphia. Fifth edition, revised and enlarged. With two full-page plates of absorption spectra in colors, four additional full-page color plates and 172 figures, of which 12 are in colors. Philadelphia: P. Blakiston's Son and Company. 1916. Price, \$2.50 net.

The author presents us with the fifth edition of his well-known work on physiological chemistry, which is made to include all the newer tests, and, in fact, is absolutely up to date. It is profusely illustrated, and the micro-photographs of the rarer products, such as aspartic acid, glutamic acid, proline, etc., must be of great assistance for verification to the investigator who is isolating these substances. It contains both classifications of proteins, adopted by the American and the English scientific societies, which differ somewhat in their grouping.

All the directions given for the isolation of various products and their identification are very complete, and while to the trained chemist must seem somewhat superfluous, will naturally be of enormous assistance to students, for whom the book is primarily written. The chapter on nucleic acid and nucleoproteins contains all of the latest results of the various investigators who have been searching this previously little known field, and can be read with profit by clinicians who can naturally trace back uric acid to its origin. In the demonstration of the presence of uricase, no cautions are introduced against the overuse of potassium hydroxide, which, as is well known, will produce the same effects as the enzyme which is being studied.

That portion of the book which is devoted to gastric digestion and analysis is very complete, and the fractional method of removal of the gastric contents from the stomach, which has been so carefully investigated by the author and his students, has been given full attention. In the chapter on feces, as is usual, the greater amount of attention is given to microscopic examination and quantitative determination, employed not for clinical purposes, but for studies in metabolism. The chapter on blood analysis contains all the newer methods of quantitative determination of urea, uric acid, sugar and creatinin in the blood, which have so largely replaced the measurement of these elements in the urine. The chapter on urine leaves nothing to be desired in its completeness and the thoroughness with which all tests and their value are given. A well-arranged table of reagents needed in the various tests employed in the book is given at the close. On the whole, this work has not only maintained its previous reputation, but has added new laurels.

# THE BOSTON Medical and Surgical Journal

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States; \$6.50 per year for all foreign countries belonging to the Postal Union.

An editor will be in the editorial office daily, except Sunday, from twelve to one-thirty p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, Manager,  
126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

## THE EPIDEMICS OF POLIOMYELITIS.

THE epidemics of poliomyelitis in New York and Massachusetts have continued to extend during the past week. On July 25 the total number of cases in New York City amounted to 3098, and the deaths to 647. In New York State, outside the city, there was on July 29, a total of 380 cases and 39 deaths. It is announced by the State Health Department that three new temporary laboratories are to be established to aid in combating the disease. At Poughkeepsie, N. Y., and in its suburb of Arlington, there had been, on July 25, 13 cases and five deaths, and it is believed that the reopening of Vassar College will be forbidden until the epidemic is at an end. At Oyster Bay, L. I., an investigation of sanitary conditions has been made by a local committee of citizens. Four cases have already occurred in this town. More rigid quarantine measures have been instituted in New York City, and no child

under 16 is now allowed to leave the city without medical inspection, a fortnight's quarantine and a health certificate issued by the federal authorities. In addition to the federal officials whose names were noted in last week's issue of the JOURNAL, as being in charge of the work in New York, the following surgeons of the United States Public Health Service were ordered to that city on July 21: Dr. W. J. Tettus, Dr. H. W. Witkes, Dr. D. E. Robinson, Dr. R. A. Herring, P. C. Kalloch, Dr. R. A. Kearney, and Dr. L. O. Weldon.

In Massachusetts the total number of cases on July 30 amounted to 95. Of these, there were eleven each in Westfield, North Adams, New Bedford and Worcester, and 9 in Boston. New foci of the disease have developed at Adams, Fitchburg, Barnstable, Hingham, Quincy, Revere and Taunton. The condition at Westfield is apparently the most serious, since the proportion of cases here to the total population is nearly as large as in New York City. Parents throughout the State have been warned by the Health Department not to take their children to either Westfield or North Adams.

In New England, outside of Massachusetts, there have now been in Connecticut, 118 cases, of which 19 were in New Haven, 12 in Bridgeport, and four in Derby. There have been three deaths from the disease in Bridgeport, two in Meriden, and one each at Windsor Locks and Milford. In Rhode Island there have been 25 cases, of which eight have been in Providence. On July 28 two cases were reported in Keene, N. H.

Outside New England, the largest focus of the disease is in Illinois, where on July 24 the total number of cases reached 73, with three deaths. Twenty of these cases were in Chicago. In Iowa there have been 14 cases and three deaths. From Elizabeth, N. J., was reported, on July 24, one of the first adult deaths from the bulbar type of the disease.

In the weekly report of the United States Public Health Service for July 14, 1916, was presented a complete tabulated statement of the prevalence of the disease throughout the country on that date, but these figures have since been so rapidly modified as to be of little present interest. In the same issue is an admirable summary by Dr. Wade H. Frost of what is known of the cause of the disease, the means of its transmission, and its epidemiological characteristics. Dr. Frost concludes that, on the

whole, the experimental evidence taken alone, while not excluding other means of transmission, points to the conclusion that poliomyelitis is a contagious disease spread from person to person through interchange of infectious secretions, the sources of infection being the clinically definite and clinically indefinite acute cases of poliomyelitis, convalescents, and passive human carriers.

In the weekly bulletin of the Health Department of the City of New York for July 8, is published a valuable statement describing atypical forms of anterior poliomyelitis and the use of lumbar puncture in their diagnosis. As a rule, poliomyelitis is regarded by the laity and by physicians alike as an acute disease, characterized by the early appearance of a more or less extensive flaccid paralysis. It has, however, widely varied manifestations. Wickman has classified the disease under eight types: 1, spinal poliomyelitis; 2, Landry's; 3, bulbar or pontine; 4, encephalitis; 5, ataxic; 6, polynuritis; 7, meningitis; 8, abortive. The simpler classification of Peabody, Draper and Dochez, from the Rockefeller Institute, recognizes three types: 1, abortive cases without paralysis; 2, cerebral cases with spastic paralysis; 3, bulbo-spinal cases. Wickman considers that from 25 to 56% of the cases are abortive. These cases are likely to escape recognition and are, therefore, most important in their relation to public health, from their likelihood of spreading infection. The symptomatology of this group of cases is further discussed in the *Bulletin* as follows:

"The initial symptoms are very like those of the paralytic cases: fever, hyperesthesia, drowsiness, headache, vomiting, varying degrees of stiffness of the neck, Kernig, positive Maeween. Seen during the first twenty-four or thirty-six hours, the diagnosis from epidemic meningitis can be made in no way except by lumbar puncture, and even this is sometimes confusing by the microscopic examination, as the fluid at this stage may be slightly turbid. The diagnosis from other acute infections of childhood depends to some extent on the greater degree of hyperesthesia and also on the examination of the spinal fluid, which in meningism, with other diseases, is normal. Recovery may take place in a few days. No diagnosis may be made unless expert consultation is obtained early. On the other hand, the symptoms may run on for two or three weeks. There often develop loss, diminution or inequality of the knee jerks and loss of the pupillary reflexes. At this stage the differential diagnosis from tuberculous menin-

gitis is very difficult, and lumbar puncture, while helpful, is by no means positive, the fluids in the two conditions being often very similar. In many cases there is a varying degree of weakness, often transient, and slight facial palsies are frequent. These abortive cases very evidently constitute the most dangerous foci for the dissemination of the disease.

"A very unusual manifestation of poliomyelitis is blindness. The Meningitis Division of the Department of Health has seen two such cases, one being in the present epidemic. In the first case, the vision was restored at the end of about three months. The second was a quite recent case and the blindness still persists. Cases with the bulbar type of paralysis, with difficulty in speaking and swallowing, are not uncommon in this epidemic and have, in some instances, been diagnosed as croup. In a fairly large number of cases, a rapidly ascending type of paralysis has been present, involving the muscles of respiration and ending with death. Some of these, when seen late, after pulmonary edema has developed, have been diagnosed as bronchopneumonia. The fatalities of the present epidemic have been largely due to these two types of the disease.

"The spinal fluid in poliomyelitis is usually clear and increased in amount. The albumen and globulin are increased in varying degrees, and there is usually a good reduction of Fehling's. The cellular increase ranges from slightly above normal to over 900 cells per cubic centimeter. Early in the disease the cells may be 50% or more polymorphonuclears. Later there are usually 90% or more mononuclears. There are frequently large mononuclear cells that seem somewhat characteristic of these fluids.

"Two rather unusual varieties of fluid are sometimes seen, probably the result of an extremely pronounced hemorrhagic condition. In one type the blood is evidently fresh, and is uniformly admixed with the spinal fluid, thereby differentiating it from blood obtained from the accidental puncture of a vein. Evidence of an older hemorrhage occurs in the second type, which presents a yellow fluid, coagulating spontaneously."

From July 5 to 8 a convention of Vermont health officers, held at Burlington, Vt., was devoted particularly to a discussion of poliomyelitis, upon which special research has been conducted at the University of Vermont College of Medicine. Papers were presented by Drs. Harold L. Amoss of the Rockefeller Institute and Robert W. Lovett of Boston. Since the epidemic of 1914, the disease has largely disappeared from Vermont, and in the effort to prevent its reintroduction, the State has established a rigid quarantine exclusion against per-

sions coming from New York City. Previous epidemics of poliomyelitis in the United States have been recorded; in Louisiana in 1841, and in other parts of the country in 1880, 1884, 1885, 1889, 1890, 1895, 1899, 1905, 1907, and 1912. Between 1905 and 1909 there were 8054 cases in the United States, representing five-sevenths of all the reported cases in the world during that quinquennium. In 1907, there were 2500 cases in New York, and in 1910, 1000 cases in the United States. The most serious previous epidemics in Massachusetts were in 1907 and 1912.

### CENTRAL CONTROL OF TUBERCULOSIS.

THE prevention of tuberculosis is so large a problem in preventive medicine that the considerations surrounding it can no longer be individual ones, but only central or communal. Public campaigns against tuberculosis have their chief value in guiding the public in their demands for the betterment of those conditions which are known to be such prolific causes of tuberculosis. Individual considerations and individual methods of care and prevention are factors in the general problem only in a comparatively small degree; and there can be very little feeling of security even in the knowledge that the lessons of prevention had been brought home to the conscientious individual. The carrying out of preventive measures by the individual depends for its efficacy upon the always variable and intangible will and comprehension of the points involved. Usually, however, those whom it is desired to reach most are quite out of reach because of general ignorance and low scale. For this reason every comprehensive investigation points to the community in its police capacity as the center from which changes must emanate if this problem is to be solved. Conditions must be so changed in the community that the personal factor will be a negligible element. The changes enforced must be in the industries—along sanitary lines, in better housing, in general cleanliness, raising of economic conditions, restriction of the drug and alcoholic consumption, central notification of all cases, better care of incipient cases and so forth. To be sure these measures require the individual coöperation, but the enforcement must be central.

In an exhaustive survey by Robinson and Wilson (*Public Health Bulletin, No. 73*) of conditions probably concerned in causing the unusually high incidence of tuberculosis in the city of Cincinnati, they found that in respect to the many industries located therein, there were no causes inherent in the occupations which helped in this increase, but that there were a great many deleterious factory influences, all remediable, to which this increase could be in part traced. Of the cases of tuberculosis found in the industries about 19.05 per cent. could be ascribed to one or another deleterious factory influence. These influences included insufficient space, insufficient toilet, washing, lighting and other facilities. The one prominent working element which seemed such a pertinent factor in the development of tuberculosis was the speeding up demanded in certain occupations. However, in 62 per cent. of the cases found in the industries there was a distinct hereditary factor, and about 19 per cent. of the cases were traceable to poor housing conditions. The hereditary element and the housing element are not distinctly separable, but overlap each other. A very large part of the apparently hereditary element is a housing one, in which the poor housing is the direct cause of the subsequent as well as the primary cases. The hereditary cases are really infections from the same source.

It is a significant fact that as much as 13 per cent. of the cases can be directly attributed to alcoholic excess; in spite of the still very popular belief that alcohol is curative, and not provocative of tuberculosis. Indeed, excesses of all kinds can be placed in this category. Abuse and excess, whether industrial or otherwise, as well as poor hygienic conditions, stand out prominently as causing tuberculosis in the individual and in the community. A community must make ample provisions for its growth and must curb abuses if it would maintain a high standard for health. It was found that in a city like Cincinnati where the growth of the city was rather slow, too slow to demand rapid and radical changes in its dwelling accommodations, as in a more rapidly growing city, and where as a result the excess population was accommodated in renovated but not enlarged building accommodations—where old buildings were made to accommodate more people than intended,—the rate of tuberculosis rose more rapidly than in cities where there was more congestion because of a more rapid growth.

## WELFARE WORK AMONG INDUSTRIAL CORPORATIONS.

THE August number of *The Modern Hospital* is published as a special issue, consisting of a symposium on welfare work among industrial corporations. The purpose of the issue is to provide valuable material for use by corporations in the way of first-aid study, emergency hospital, and welfare work.

The three phases into which welfare work is divided, or rather the three purposes for which it should be undertaken, are considered in this symposium to be as follows:

1. To make employees healthy, comfortable, and happy, in order that they may achieve the highest efficiency in their work.
2. To help employees prepare for the day when they are prevented from being bread winners, so that dependents on them may be provided for in case of sickness or disability.
3. To provide entertainment, recreation, and interesting groupings, in order that the employees of the corporation may have mutual interests which will enhance their loyalty and teamwork.

There are articles on various features of this work by Dr. Thomas Darlington, Dr. Samuel Lambert, Dr. S. S. Goldwater and many non-professional writers. In view of the prominence now being given to conditions of industrial welfare, this valuable special number of *The Modern Hospital* is particularly called to the attention of physicians.

---

## MEDICAL NOTES.

LONDON DEATH RATES IN MAY.—Statistics recently published show that the total death rate in London in May, 1916, was only 12.9 per thousand inhabitants living. Among the several districts and boroughs, the highest rate was 18.6 in Finsbury, a crowded central slum, and the lowest was 8.5 in Stoke Newington, an open suburb on the north.

WELSH NATIONAL SCHOOL OF MEDICINE.—The foundation stone of the new buildings of the Welsh National School of Medicine at Cardiff was laid over a year ago by Lord Pontypridd. Sir William Thomas had given over £90,000 towards the completion of these buildings and over £250,000 more had been raised by Col. Vaughan. The war, however, has so far interfered with the project that further work on the buildings is indefinitely postponed. "This post-

ponement," says a recent issue of the *Lancet*, "is naturally a source of keen regret and must cause anxiety to all who have at heart the cause of medical education and who view with dismay the probable shortage of medical men in the near future."

PREVALENCE OF MALARIA, PELLAGRA, SMALL-POX, AND TYPHOID.—The weekly report of the United States Public Health Service for July 14, 1916, states that during the month of May, there were in Arkansas, 390 cases of malaria, 62 of pellagra, and 22 of typhoid fever. In Kansas during the same period there were 230 cases of smallpox, and 56 of typhoid.

AMERICAN DENTAL ASSOCIATION.—The twentieth annual meeting of the American Dental Association was held in Louisville, Ky., from July 24 to 27. At the second day's session, the subjects for special discussion were "the relation of mouth infections to general health and the importance of insuring prompt and permanent dental repair." Principal addresses were made by Dr. Thomas B. Hartzell of Minneapolis, Dr. John R. Callahan of Cincinnati and Dr. Weston A. Price of Cleveland. On July 27, Dr. L. L. Barber of Toledo was elected president, and Dr. Waldo L. Boardman of Boston a trustee for the ensuing year. The meeting of 1917 is to be held in New York City.

THE ASSOCIATED OUT-PATIENT CLINICS OF THE CITY OF NEW YORK.—The formation of an association of out-patient clinics of New York and Brooklyn about three years ago was recorded in the *JOURNAL* at that time with a statement of its aims which were:

1. The coördination of the work of existing dispensaries and out-patient clinics.
2. The elimination of unworthy applicants for treatment.
3. The promotion of proper standards of treatment.
4. The promotion of economy and efficiency in dispensary management.

On December 31, 1915, the membership of the Association numbered fifty-two clinics. The third annual report, for the year 1915, has recently been issued. The chief accomplishments stated therein are the establishment of two new sections of the Association, the Section of Surgical Clinics and the Section of Neurological Clinics. A statement of the required standard of a surgical clinic, prepared by that section, is given in detail and covers the equipment of a surgical clinic, the kind of patients to be treated in a surgical out-patient department, social service and visiting nursing and the history system. A similar standard has been drawn up by the Section of Neurological Clinics. Following a survey of the genito-urinary and syphilis clinics of Manhattan, additional suggestions were made to the already existing standard for clinics of that kind.

During the past year a chart, similar to the one published in the Second Annual Report, was prepared, showing the pathologic effects resulting from the inhalation of dust incident to a certain number of industries. The chart published last year in the annual report related to poisonous substances incident to industries in New York, but did not include dusts. The new chart was prepared by the executive secretary, and endorsed by Dr. W. Gilman Thompson, professor of medicine at Cornell University. The committee believes that the publication of this chart, in addition to the previous one, will be helpful to the clinics in the diagnosis of industrial diseases.

By the courtesy of the Division on Industrial Hygiene of the Department of Health, this chart will be published by the department, and the Association was requested to help the department in the distribution of this chart through the medium of the Annual Report.

#### EUROPEAN WAR NOTES.

**PRIZE FOR MECHANICAL HAND APPARATUS.**—A generous donor, who wishes to remain anonymous, has offered to the National Society of Surgery of Paris, a prize of 50,000 francs to be given to "the maker of the mechanical apparatus supplying the place of the hand best. All competitors must belong to allied or neutral nations. They are to present to the Society mutilated men who have been using their apparatus for at least six months. The Société de Chirurgie will experiment each apparatus on mutilated men for the length of time it thinks fit. The apparatus rewarded is to remain the property of its inventor. The competition will be closed two years after the end of the war."

MM. Faure, Kirmisson, Quénu, Rieffel and Rochard, who make up the committee elected by the Société de Chirurgie, inform the public of the condition of the competition as stated by the donor and beg any person wishing to compete to send his memoir and apparatus to M. le Secrétaire Général de la Société Nationale de Chirurgie, à Paris, 12, rue de Seine

**AMERICAN NURSES IN RUSSIA.**—The work of enrolled graduate American Red Cross nurses in Russia is the subject of a letter from Mr. William Warfield, formerly an attaché of the American Embassy in Petrograd, and now chargé d'affaires for the United States in Sofia, Bulgaria, addressed to Miss Jane A. Delano, Chairman of the National Committee on Red Cross Nursing Service. The letter follows:

"While acting as an attaché of the Embassy in Petrograd, specially assigned to war relief work, I had occasion, as you know, to see a great deal of the members of the American Red Cross units in Russia. It gives me great pleasure to take advantage of this opportunity to say that the nurses attached to these units have been the greatest credit to the organization, and to the

country they represent. Their professional efficiency is not only unquestioned but has excited a great deal of comment in medical circles, having been mentioned to me frequently by the Russian surgeons. Personally, by their devotion to duty and their splendid organization and discipline, these ladies have been a credit to American womanhood and its ideals. I do not hesitate to say that they have had an influence for good quite apart from mere professional services.

"I wish especially to express my appreciation of splendid work done by the group that worked largely under my personal supervision at Irkutsk. Their work there being non-professional in great part shows that the type of woman you are sending out is not only a good nurse but an all-round resourceful woman as well."

**WAR RELIEF FUNDS.**—On July 29 the totals of the principal New England relief funds for the European War reached the following amounts:

Belgian Fund .....	\$139,778.15
French Wounded Fund .....	105,609.07
Serbian Fund .....	101,609.07
Armenian Fund .....	100,115.00
French Orphanage Fund .....	57,775.03
Surgical Dressings Fund .....	41,205.87
Belgian Tobacco Fund .....	32,433.40
Faical Hospital Fund .....	23,765.51
Italian Fund .....	21,102.84
Permanent Blind Fund .....	3,305.13

#### MEXICAN NOTES.

**HOSPITAL NEEDS IN TEXAS.**—The American Red Cross headquarters in Washington on July 25 received very interesting reports from its special agent in El Paso, Texas, Dr. Eugene A. Crockett, of Boston. After stating that very little has been received at El Paso in the way of gifts and comforts for the soldiers he says that as far as their serious material needs are concerned very little is required. Dr. Crockett says:

"I have now seen quite thoroughly the camps in the vicinity of El Paso, both regular and militia; also the camps at Columbus, N. M., and on the line of communication south as far as Colonia Dublan, Mexico, where I spent two days, and from where I have just returned.

"There is no doubt in my mind but that the condition of the troops in general is excellent. The sanitation of the camps at Columbus, N. M., Ojo Fredrico, and Colonia Dublan is far superior to anything that I have ever seen, and I think about as near perfect as is possible to attain. The health of the troops is consequently excellent, very little serious sickness, and plenty of available beds in the hospitals, except here at Fort Bliss, where the immense number of volunteer troops has certainly crowded Col. Straub a

good deal. There is nowhere any lack of medical supplies or hospital necessities, and I don't think it necessary to ship any such things down here, nor, as I wrote Colonel Kean yesterday, can I see any possible use of civilian base hospitals of the Red Cross at the present time."

**MASSACHUSETTS AMBULANCE COMPANY No. 2.** In last week's issue of the JOURNAL we noted the organization of the Second Massachusetts Field Hospital. The Massachusetts Ambulance Company No. 2 has also been recruited to full strength to accompany this hospital and will also be mustered into Federal service. It consists of seventy-five non-commissioned officers and the following commissioned officers: Captain Oscar A. Dudley, Lieutenants James A. Lyon and N. M. Scott.

**WORK OF MASSACHUSETTS DENTAL UNIT.**—Since the mobilization of the Massachusetts militia, a dental unit under command of Dr. Theodore E. LaFayette has been at work among the soldiers who camped at Framingham, from July 1 to July 21. On the latter date this unit completed its services and made the following report to the Surgeon-General.

"To the Surgeon-General: Please find enclosed the information which you requested. In behalf of the dental unit I desire to thank you and the Medical Corps for the kind treatment extended to us at the muster field. A great many improvements could be made in our dental clinic—such as the lighting, sterilization and water supply, but owing to the prevailing uncertainty of time at the camp we tried to make the most of what we had. The work at the field has been of very great interest to us and if we have done nothing more than aid a few to enter or continue in the service of the United States Army we shall have felt our time well spent. Army life is fascinating and it is with regret that we feel our stay is nearly over—but look forward with the fond hope that some day we may be in the service as dental surgeons.

"At any rate we are all proud to have served our country in a dental unit which we feel is the first of her kind in the history of the American army. Whether in the service or in private life we shall always stand ready and eager to serve America in whatever capacity she may call us.

"Thanking those who have so kindly given us the opportunity to be of some service to our country and for the kind treatment at the muster field, I beg to remain,

"For the Dental Unit,

"Sincerely yours,

"(Signed) THEODORE E. LAFAYETTE, D.M.D."

TO THE SURGEON-GENERAL.

"Days on Duty—Twenty (July 1-21).

"Seven operators constantly on duty (visiting): Dr. Theodore E. LaFayette, Jr., Mr.

Harold W. Crowell, Dr. Stanley C. Keene, Dr. Angelo Lucibio, Dr. John Thomas, Dr. Roy Smith, Dr. Walter Kennedy.

"Chairs—Nine in good condition; one with broken legs.

"Gas Machine—One Teter machine ( $N_2OxO$ ).

Patients examined.....	3126
Cleaning .....	900
Cement .....	521
Silver .....	675
Extractions .....	1273
Gas $N_2OxO$ .....	219
Chloroform .....	2
Novocain .....	176

Treatments:

Pericementitis (loose bridge-work) ....	11
Alveolar abscess .....	37
Antrum infection (x-ray taken, case cleared) .....	1
Plates (partial) .....	37

Month lesions noted:

Lichen planus .....	2
Active pyorrhea .....	17

Material used:

48 bottles of white copper cement.	
24 bottles of white silver alloy.	
5 pounds of mercury.	
24 tubes of eocaine.	
50 "E" novocaine tablets.	
1 gallon sterile water.	
1 box temp. stopping.	
1 box C matrix.	
2 sets assorted burrs.	
11 large tanks of $N_2O$ .	
7 small tanks of oxygen.	
1 gallon of alcohol.	
2 quarts liquor antiseptic.	
50 corrosive sublimate tablets.	
11 pounds pumice.	
1 quart glycerin.	
48 clean white coats.	
15 bottles cleanoid solution.	
7 rolls of rubber dam."	

**MASSACHUSETTS RELIEF FUNDS.**—On July 29 the totals of the principal Massachusetts relief funds for soldiers on the Mexican frontier reached the following amounts:

Base Hospitals Fund .....	\$77,747.20
Volunteer Aid Fund .....	73,021.44
Special Aid Fund .....	10,008.40
Home Relief Fund .....	2,193.00
Eighth Regiment Fund .....	1,985.00

BOSTON AND NEW ENGLAND.

**THE WEEK'S DEATH RATE IN BOSTON.**—During the week ending July 29, 1916, there were 169 deaths reported, with a rate of 11.59 per 1000 population, as compared with 222 and a rate of 15.47 for the corresponding week of

last year. There were 25 deaths under 1 year, as compared with 39 last year, and 38 deaths over 60 years of age, against 57 last year.

During the week the number of cases of principal reportable diseases were: diphtheria, 27; scarlet fever, 10; measles, 77; whooping cough, 31; typhoid fever, 6; tuberculosis, 54.

Included in the above were the following cases of non-residents: diphtheria 6; scarlet fever, 2; tuberculosis, 5.

Total deaths from these diseases were: diphtheria, 1; measles, 5; tuberculosis, 18; whooping cough, 1.

Included in the above were the following deaths of non-residents: diphtheria 1; measles, 1; tuberculosis, 18.

**TYPHOID CARRIERS.**—The history of a family of typhoid carriers is told in the monthly bulletin of the Connecticut State Board of Health. The carriers in this instance were the immunized parents of children ill with typhoid. The two children, who lived on farms near Hartford, were taken sick with typhoid the first week in August.

"Each farm was sending milk to the city, so during the sickness the cows were boarded at another farm. In one case the infection of the milk had already been accomplished, and on this route sixty-one cases developed in the next four weeks. This figure shows at once how unpasteurized milk may be an unknown danger to its consumers.

"At the farms the members of the families were all immunized by the physician. The cases had an uneventful run, and by the end of August the children were apparently well. Before returning the cows to the farm it was deemed best to make sure that all the persons on the premises were free from infection. The parents, who took turns in nursing in both the families, the other two children and the children who had been sick were found all to be carriers, but three other adults in the families, less closely in touch with the patients were cleared. The two sick children cleared themselves of typhoid indications by the first of October, two months after the infection had been discovered, and the other two children were free shortly afterwards. But all four parents carried the disease germs till December, two months longer, although they had never had the fever.

"This observation shows a new way in which care must be exercised in dealing with typhoid, for there is danger of spreading the disease through the fact that immune attendants may become carriers."

**BOSTON BABY HYGIENE ASSOCIATION.**—A recent report of the Boston Baby Hygiene Association states that during the past week 1891 infants were under care by the Association, be-

ing 200 more than during the corresponding week of last year. Of these babies, 695 attended the well baby conferences and 1286 were visited in their homes by the sixteen nurses maintained by the organization.

**NEW PATHOLOGICAL LABORATORY.**—The July issue of the Bulletin of the Massachusetts State Board of Insanity reports that "on June 7 the State Board voted to establish, with the approval of the trustees of the Grafton State Hospital, a branch of the Pathological Service at the Summer Street department of the Grafton State Hospital, and there to make a new center for the investigation and treatment of brain syphilis.

"On the same date the Board voted to appoint Dr. Douglas A. Thom as assistant pathologist to the Board, to date from July 1, the Grafton State Hospital having kindly consented to provide for his maintenance and housing at the Worcester department. The major part of Dr. Thom's work will be in connection with the syphilis experimental treatments in special wards for male and female patients, as arranged for by Dr. May. The re-arrangement of the Summer Street building at Worcester will permit ample accommodations for the new branch of the Pathological Service, and includes an office for the assistant pathologist, space for the technician and room for the stenographer.

"This extension of the service will also relieve Dr. M. M. Canavan, who has been very much overworked by the development of the service. Dr. Thom will be able to undertake and investigate the work of accidents and sudden deaths for the middle and western parts of the State, namely, in six institutions.

"This plan of the State Board and the pathologist to establish a separate Psychopathic Department for the middle and western parts of the State has been made possible through the active and effective interest which Dr. James V. May and the trustees of the Grafton State Hospital have taken."

**THE LONG ISLAND HOSPITAL, BOSTON.**—The nineteenth annual report of the Boston Infirmary Department for the year ended January 31, 1916, states that the average population of the Hospital, 1014, shows an increase of fourteen over the previous year. In August the people housed at the Charlestown Almshouse were transferred to Long Island. Of the 112 persons who were in the institution at the time of removal, all but 13 men and three women have been received at the Long Island Hospital. The necessity for laboratory facilities at the Hospital is emphasized and suitable accommodations urged for the establishment of a laboratory where the abundant clinical material of-

ferred may be utilized. The opportunities at Long Island are exceptional for the thorough study of disease in many of its distressing forms, but without proper facilities, productive work cannot be accomplished.

**HOSPITAL BEQUESTS AND GIFTS.**—The will of the late Sarah E. Stickney, who died in Newburyport, Mass., on June 25, was filed on July 24 in the Essex County Probate Court at Salem, Mass. It contains bequests of \$500 each to the Columbia Hospital, of Columbia, S. C., and to the Anna Jacques Hospital of Newburyport.

The recently filed will of the late Caroline M. Dana, who died on July 22, contains bequests of one-tenth of her estate each to the Industrial School for Crippled and Deformed Children, the New England Hospital for Women and Children, and the Children's Hospital, Boston.

Mr. Frederick Fanning Ayer, of Lowell, Mass., has recently made to the Lowell General Hospital an additional gift of \$200,000, of which he requests that \$130,000 be used to construct a new hospital building 200 feet in length and two stories high, to afford an operating room and living accommodation for twenty nurses. The income of the remaining \$70,000 is to be used for the general purposes of the hospital. The Lowell Hospital at present accommodates 60 patients, but with the construction of further new buildings, for which the plans have been already drawn and approved, it will accommodate 160. The total of Mr. Ayer's gifts to the Hospital now amounts to \$620,000.

The will of the late Alice G. H. Dwinell, of Brookline, Mass., which was recently filed at the Norfolk County Probate Court, contains bequests of \$200 each to the Boston Lying-in Hospital and the Industrial School for Crippled and Deformed Children.

The will of the late Ellen Dunn of Salem, Mass., who died on July 12, was probated on July 25. It contains a bequest of \$200 to the Carney Hospital.

**TUBERCULOSIS SURVEY.**—It is announced that the National Association for the Study and Prevention of Tuberculosis purposes to expend \$100,000 for an experimental three-year survey of tuberculosis in two selected towns of Massachusetts and New York. Among the towns under consideration are Canandaigua, Johnstown, and Patchogue, N. Y., and Framingham, Wrentham, and Norwood, Mass. In each town selected, every case of tuberculosis and every contact will be examined frequently and kept under constant observation. The purpose of the experiment, which will be in charge of Dr. Donald B. Armstrong of New York City, and Dr. Edward R. Baldwin, of Saranac Lake, N. Y., is to determine the absolute and relative values of various methods of combating the disease.

## Miscellany.

### NEW METHOD OF MAKING ANTI-HOG-CHOLERA SERUM.

A NEW method of preparing anti-hog-cholera serum, which permits the economical production of a clear sterilized product, has just been described in the *Journal of Agricultural Research* of the United States Department of Agriculture. The advantage claimed for the new method is that it makes possible the production of an anti-hog-cholera serum which can be quickly sterilized by heat to a point that will absolutely kill any germs of foot-and-mouth disease, and so yield a serum that is absolutely safe, even if taken from a hog which might harbor foot-and-mouth disease, and yet give no indication of being infected.

The method, as described by its discoverers, Dr. Marion Dorset and R. R. Henley, of the Biochemic Division, Bureau of Animal Industry, consists in adding a slight amount of an extract from ordinary white navy beans to the defibrinated hog-cholera-immune blood, which has been the form of the serum used in the past. The addition of this bean extract causes the red cells of the blood to agglutinate, and when the mixture is whirled on a centrifuge the red cells pack together and form a rather stiff jelly-like mass. It is then possible to pour off a clear serum, leaving behind the red cells, which play no part in preventing hog cholera, and which, in fact, simply tend to dilute the serum and render its sterilization by heat impracticable. To increase the yield of clear serum the discoverers added a small amount of ordinary salt and found that they obtained from 70 to 74% of clear serum. The clear serum thus obtained it was found could be heated for 30 minutes at a temperature of 60 degrees Centigrade without changing its consistency or lessening in any way its effectiveness in preventing hog cholera. The heating to this point for this time is more than sufficient to kill any germs of foot-and-mouth disease which might accidentally be present. Practical tests with hogs show that probably all of the antibodies useful in combating hog cholera were retained in the serum, and the red cells extracted contained so few, if any, of these valuable bodies as to make the residue of red cells useless in preventing the disease.

Before the clear serum was developed, many attempts were made to sterilize by heat in a practicable way the ordinary defibrinated blood. It was found, however, that heating the old product up to 60 degrees Centigrade resulted in more or less complete coagulation of the defibrinated blood and in the destruction of the serum so far as its commercial worth is concerned. It was found that the highest temperature that could be used was 50 degrees Centigrade, and it was necessary to keep the old

serum at this temperature for 12 hours to make certain that the virus of foot-and-mouth disease was killed. Heating serum at a steady temperature over this long period in ordinary practice is difficult and too expensive.

Attempts also were made to make a clear serum by centrifugalizing. It was found, however, that while the centrifuge would separate to some extent the red cells, they were in such shape that it was difficult to separate the serum completely. An important quantity of antibodies was left behind in the red clot, and the resulting product was a cloudy rather than a clear serum. With this process, moreover, it was possible ordinarily to secure only about 50% of serum. Under the new method it is possible to secure as high as 74% of clear serum, which, in actual test, has proved to be fully potent. This clear serum, moreover, can be completely sterilized in 30 minutes, whereas the old serum had to be heated steadily for 12 hours.

*The new form of serum, as far as the Department knows, is not yet being made or put on sale by the commercial serum laboratories. As this process was discovered by the Federal government, any one in the United States is free to use it.*

#### UNITED STATES MEDICAL RESERVE CORPS.

At the examination recently held in various cities throughout the United States the following-named medical men successfully passed the examination for appointment as assistant surgeon in the Medical Reserve Corps, with a view to subsequent examination for appointment in the Medical Corps of the Navy:

James A. Halpin, M.D., Washington, D. C.  
William D. Heaton, M.D., Wahoo, Neb.  
Aubrey M. Larsen, M.D., Salt Lake City, Utah.  
Lincoln Humphreys, M.D., Argenta, Arkansas.  
Theo. Edward Cox, M.D., Cleveland, Ohio.  
Arthur W. Houghland, M.D., Minneapolis, Minn.  
Carroll H. Francis, M.D., Camden, N. J.  
Harold L. Jenson, M.D., San Francisco, Cal.

#### SOCIETY NOTICE.

AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.—The next annual meeting of the American Electro-Therapeutic Association will be held at the Hotel Marlborough, New York City, September 12, 13 and 14, 1916.

#### APPOINTMENTS.

ROCKEFELLER INSTITUTE.—The Board of Scientific Directors of the Rockefeller Institute for Medical Research announces the following promotions and appointments:

*Dr. Alphonse R. Dochez*, hitherto an associate in medicine, has been made an associate member.

*Dr. Henry T. Chickering* has been appointed resident physician in the hospital to succeed Dr. Dochez.

The following have been made associates:

*Dr. Louise Pearce*, pathology and bacteriology.

*Dr. Frederick L. Gates*, pathology and bacteriology.

The following have been made assistants:

*Dr. Oswald Robertson*, pathology and bacteriology.

*Ernest Wildman*, chemistry.

The following new appointments have been made:

*Dr. Rhoda Erdmann*, associate in the department of animal pathology.

*Dr. Rufus A. Morrison*, assistant in medicine and assistant resident physician.

*Dr. John Northrup*, assistant in the department of experimental biology.

*Dr. Jean Oliver*, assistant in the department of pathology and bacteriology.

*Dr. Ernest W. Smillie*, fellow in the department of animal pathology.

*Dr. William D. Witherbee*, assistant.

Hardolph Wasteney, hitherto an associate in the department of experimental biology, has accepted an appointment as associate professor of pharmacology in the University of California.

#### RECENT DEATHS.

DR. EDWARD FRANCIS HODGES, who died recently at Cavendish, Vt., of heart disease, was born in Boston on Aug. 1, 1851. As a boy he attended the Boston Latin School, in the days of Dr. Francis Gardner, and under Dr. Soule. He graduated from Harvard with the class of '71, and then studied medicine in Washington. He received the degree of M.D. from Georgetown University in 1874 and from Harvard in 1877. In 1880 Dr. Hodges moved to Indianapolis, Ind., where he continued in the practice of his profession until he gave up active work, several years ago.

Dr. Hodges was a Fellow of the Massachusetts Medical Society from 1875 until 1888. He was professor of obstetrics in the Medical College of Indiana from 1884 to 1905, and professor of obstetrics in Indiana University from 1905 to 1912.

Dr. Hodges is survived by his widow, formerly Miss Laura Fletcher, and one son, Dr. Fletcher Hodges, a physician in Indianapolis.

DR. SIR VICTOR A. H. HORSLEY, the celebrated British surgeon, died of heat stroke in Mesopotamia on July 16. He was born in 1857 and professionally was particularly noted for his work in cranial surgery. He was knighted in 1902, and since his retirement in 1906 had been emeritus professor of clinical surgery and consulting surgeon at the University College Hospital of London.

DR. CHARLES R. E. KOCH of Chicago, who died recently at Newton, Mass., was born in Polish Prussia in 1834 and migrated to the United States as a child. In 1860 he enlisted in an Illinois regiment with which he served throughout the Civil War. Later he studied dentistry and practised his profession in Chicago for many years. He was, for a time, secretary of the dental department of Northwestern University and had served as inspector-general and adjutant-general of the Illinois National Guard. During the Spanish War he organized and maintained a regiment at his own expense. He was a member of many dental organizations and was the author of a history of dentistry and of several works of military history. He is survived by his widow.

SIR WILLIAM RAMSAY, the celebrated British chemist, who died on July 23, at Beachcroft, Hazelmere, Bucks, England, was born in Glasgow on October 2, 1853. He became president of the British Association for the Advancement of Science and received the honor of knighthood in 1902. In 1904 he was awarded the Nobel prize in chemistry. He is chiefly noted for his researches on radium in 1907 and for his theory of the transmutation of elements announced in 1913.

DR. CLARENCE A. KIRKPATRICK of Philadelphia, a medical missionary at Namkham, in the Province of Burma, India, has died there recently. He was a graduate of the University of Pennsylvania.

## Original Articles.

### THE DIAGNOSIS AND MANAGEMENT OF VASOMOTOR DISTURBANCES OF THE UPPER AIR PASSAGES.\*

By J. L. GOODALE, M.D., BOSTON.

It has been known for some years that an individual sensitized to a given proteid may exhibit a characteristic reaction if the proteid is brought in a soluble form in sufficient concentration into contact with a scratch of the skin. In the present connection it is of importance for us to recognize and interpret correctly the significance of this skin reaction. I shall, therefore, briefly describe it and its various degrees of intensity.

The proteid to be tested is applied to a scratch on the skin of the arm. After five to fifteen minutes the positive reactions are indicated by varying degrees of local disturbance. These disturbances of the skin may be ranged in order of intensity as follows: In some cases the first perceptible alteration consists in a sharply circumscribed white area, not elevated, bordering the scratch for a distance of one to three millimeters. We may find in other individuals the first manifestation to consist of a slightly reddened raised area. In more pronounced disturbances the area of swelling is more extensive, and is more or less white in color, being surrounded by an area of reddening of

varying size. When this degree of disturbance appears, it is usually accompanied by itching. It may, in marked cases, attain a considerable size, the edematous area reaching two to three centimeters or more in diameter and surrounded by a centimeter or more of hyperemia.

In the course of thirty minutes, or at most one hour, the reaction fades, and only the slight trauma occasioned by the scratch is left. In the case of certain proteids there may appear on the following day an alteration at the site of the scratch characterized by appearances of inflammation rather than of angioneurotic disturbance. The skin bordering the scratch becomes reddened, slightly elevated and firm. In the course of another twenty-four hours a trace of suppuration may supervene. These disturbances disappear in two or three days. It was at first thought that these inflammatory manifestations were the result of a chance infection, but they have occurred so regularly after testing with certain proteids as to suggest a definite relationship to the proteid substance itself. They follow most frequently tests with staphylococcus *p. aureus* and albus and streptococcus *pyogenes*. Among the foods, cocoa is apt to show it.

While the occurrence of the skin reaction may be regarded as indicative of sensitization to the proteid employed, yet it is premature to say that a direct relationship invariably exists. Certain observations, for instance, made in the course of hay-fever immunization, which I have elsewhere recorded, show that there is not always a skin reaction proportionate to the intensity of the nasal and ocular symptoms.

\* Read before the American Laryngological Association, May 9, 1916, at Washington, D. C.

During the past two years over four hundred cases showing vasomotor disturbances of the upper air passages were examined by the skin test with different proteids, for the purpose of determining, if possible, the diagnostic value of this reaction, and ascertaining its relationship to the clinical manifestations. For many of these disturbances the special exciting proteid was indicated by the patient's history, as in cases of hay-fever, intolerance to fish, horses, eggs, etc., but exclusive of the hay-fever patients, the larger number gave a clinical history in which the causative agent was unknown to the patient.

Cases of vasomotor rhinitis of recognizable reflex origin and asthma from cardiac and renal disease are not included. In many instances, particularly of nasal disturbances, the diagnosis of a reflex cause, such as from the genital organs, is difficult to establish, but wherever possible a physical examination from an internist or the family physician was obtained.

*Classification of Proteids.* Recent studies have established a phylogenetic classification of animals and plants, based upon the serum reactions. As the result of the studies, chiefly of Nuttall for animals and of Metz and Gohlke for plants, we are enabled to construct a phylogenetic tree for both kingdoms. The application of these studies to our subject is considerably simplified by our ability to eliminate many members of the animal and plant kingdoms, which have no direct relation to man.

*Animals.* The primitive proteid molecule in the animal kingdom represented by protozoa exhibits a differentiation in the direction of the molluscs or shell-fish, and passing upward gives off the branch of the crustacea. Above this are the vertebrates, with the branches respectively of fishes, birds, the main trunk terminating in the mammals. In the present connection the mammalian orders which concern us are represented by the domestic animals, and by those which serve as foods, or whose skins as articles of clothing.

*Plants.* The phylogenetic tree of the plant kingdom proceeds from the bacteria upward, and divides into the monocotyledons and dicotyledons, the first being represented chiefly by the large family of grasses and by the orders of iris and lily. The trunk of the dicotyledons terminates in the order Compositae, or family to which the ragweed belongs, and gives off along its course a large number of orders, which have been shown to be of anaphylactic significance, the most important members of these being the nuts, the legumes and the rose family.

*Preparation of Material.* It is of importance to have the test material in the form in which it exists when exciting symptoms. Consequently, we should have it either in the raw or cooked state, respectively, or in both, as the case may be.

It should also be in a stable form, and as pure and concentrated as possible.

This statement is especially emphasized by the fact that we find that different persons vary widely in their degree of sensitization to a given proteid; consequently, one person may react to a proteid dilution of a given strength, while another individual sensitized to the same proteid may require a hundred or more times greater strength of the solution to elicit an equivalent skin reaction.

In the case of animals, preparations should be made both of those parts capable of entering the respiratory mucous membrane, as flying scales or hairs, and also of the serum and of those parts ordinarily ingested, such as egg and milk. Extracts from the epidermal structures are easily obtained by placing scrapings from the skin, hairs or feathers respectively, in 12% alcohol. Sterilization is accomplished after a few days by the action of the alcohol, and the suspended particles of clear filtrate may then be used. The material may be tested for its sterility, but in no case have I found it contaminated, or even after months show signs of decomposition. These extracts appear to keep without deterioration, and I have now two made from horse epidermis, which have been kept at room temperature for over a year, and are apparently as active as when first prepared.

In the case of animal foods, crude but satisfactory material is readily prepared by expressing the juices in a meat press, and subjecting them to rapid desiccation by a blower.

The same method may be followed in the case of plant material. Oils may be removed by leaching with carbon tetrachloride. Both these animal and plant extracts may then be preserved when thoroughly dry without deterioration.

The proteids of egg and milk can be obtained commercially in the form of a pure powder as egg albumen and casein respectively.

While the refinement and separation of the different proteids present in a given material is desirable and represents a field of important research, yet the above-mentioned relatively crude preparations will suffice to answer our first clinical question as to whether the individual is sensitized to the material in question.

In the present work cases were examined both with preparations made along the above lines by Dr. Turnbull in the Throat Department of the Massachusetts General Hospital, and also by pure refined proteids prepared by Mr. R. P. Wodehouse in the Botanical Laboratories of Harvard University.

*Preparation of Bacteria.* Suspension of bacteria killed by coagulation of their albumen may be injected intradermally, and the presence or absence of a reaction noted on the following day, as already practised for a number of diagnostic tests, but I have also found it possible to procure the bacterial proteids in a soluble

form capable of exciting an immediate skin reaction in the same manner as that obtained from pollen and other plant and animal extracts. At the beginning of the work, cultures were grown by Dr. C. G. Page, instructor in bacteriology at the Harvard Medical School, on agar slants, when they were exposed to ether vapor, the object sought being to kill the micro-organisms without coagulation of their albuminous constituents. After remaining in ether vapor four days, the colonies were transferred to a 12% dilution of alcohol with water, in order to extract, if possible, the proteids of the bacteria. This alcoholic dilution was chosen as it has been found by the writer to preserve best the anaphylactogenic properties of pollen and keratin extracts. The quantity of bacteria was about one-third by volume that of the alcohol dilution added; so that, on centrifuging, the bacterial bodies occupied one-third and the fluid two-thirds of the tubes. After a week, the fluids were tested on the skin of patients in the same manner as that employed for the diagnosis of plant sensitizations.

Since then a variety of methods of preparing bacteriological material has been developed by Dr. A. E. Steele of the Massachusetts General Hospital, Dr. I. C. Walker at the Peter Bent Brigham Hospital, Dr. Cleveland Floyd and Mr. H. M. Baker at the Harvard Medical School, to all of whom I am greatly indebted for the opportunity which they have given me to test preparations made with this object in view.

In the case of plant pollen, I prefer to keep it in a dry form, as it will then stay unchanged for an indefinite period. I have flowering specimens of grasses and of ragweed in my herbarium gathered over thirty years ago, the pollen of which still gives pronounced skin reactions in patients sensitized to these plants.

A method was evolved by Mr. Wodehouse for the extraction of ragweed pollen from the flower heads, which enables one to obtain it in a purer form than has hitherto been the case. Plants of ragweed are gathered in the flowering stage and the flowers stripped off. The habit of this plant is to open the flower heads in succession, and consequently at a given time some will be found to have discharged their pollen and others to be as yet unopened. After drying in air the heads of flowers were washed in carbon tetrachloride to remove oils, etc., and it was found that most of the pollen came out in the process. Very little solid matter except the pollen will pass through the muslin used for straining. The pollen grains having passed through are allowed to dry and are seen to be somewhat paler than those obtained in the natural way, the difference in color being probably due to the removal of lecithin.

The same method is applicable to the other anemophilous plants, which furnish a large amount of pollen.

We are thus enabled to obtain the pollen in a

relatively pure form and consequently can make solutions of known proteid strength. Furthermore, this material has not been subjected to the risk of change by treatment with proteid precipitants and approximates closely to the original proteids in their natural state, as they actually reach the exposed mucous membranes.

Experiments were undertaken in regard to preserving pollen and pollen extracts. As I have stated in a previous paper, a dilution of alcohol in water proved most serviceable. The important object to be attained is a solution which will check decomposition, with the minimum loss of strength of the active principle. It was found that pollen extract in 6% alcohol or less showed after a few days development of bacteria and proteid decomposition. A dilution of 8 to 10% was sufficient to check putrefaction, and if the bottle was completely filled with the solution it remained free from alteration. If, however, the bottle was frequently opened or left half full, there was a prompt invasion of the yeast organism with development of vinous odor. This was later followed by the appearance of the *Mycoderma vini* and general turbidity. Solutions from 12 to 15% could be left open without alteration and there was no development in them of the *Mycoderma*. These solutions were found to contain an unstable albumen and a relatively stable proteose. The former is readily coagulated by exposure to air, by treatment with alcohol of above 20%, and by heating to 60° C. The proteose, on the contrary, suffers but little on exposure to air, and will endure boiling without precipitation. This observation is in harmony with the familiar fact in wine-making that at the close of the first fermentation a clear fluid is present containing the albuminoids of the grape in solution. These are in part thrown down at the first racking and consequent exposure to oxygen, rendering the wine turbid, and requiring often the admixture of isinglass to effect a clarification.

For this reason pollen solutions should be kept as far as possible from exposure to air, and if in the older ones a cloudiness occurs, it should not be filtered, as thereby the albumen would be removed, leaving only the proteose in solution.

The globulins of the pollen grain were separated by Mr. Wodehouse, but were found to be without anaphylactogenic properties.

#### METHOD OF ENTRANCE OF FOREIGN PROTEIDS INTO THE BODY.

Obviously under natural conditions the mucous membranes of the respiratory and the intestinal tract afford ready means of access for these substances when inhaled or ingested, and we may consequently speak of such forms of allergy as (1) inhalation or (2) ingestion anaphylaxis.

The possible existence of a third form should be considered, namely where the symptoms may arise from (3) autolysis of bacterial proteids

when in contact with the mucous membranes. In a recent paper I have called attention to this possibility, and have shown that in certain cases of perennial vasomotor rhinitis and bronchitis, it is possible to elicit an immediate skin reaction by the application of soluble bacterial proteids to a scratch. Since this paper was written further observations have tended to confirm these views. Such cases are dependent upon the more or less periodic invasion of the mucous membranes by the bacteria to which the individual is sensitized; during the intervals of infection, the patient remaining free from vasomotor disturbance.

At least two other possible bacterial causes may exist. In the first instance it is theoretically possible that chronic septic foci, as in chronic tonsillitis, with accumulation of lacunar debris, may be the source of sensitizing proteids; also it is conceivable that the intestinal canal may permit the development of bacteria, which may undergo autolysis, and the consequent liberation of proteid material which is anaphylactic for the individual.

The above system of classification is a tentative one, and while for certain portions we may believe that we have sufficiently confirmatory evidence, we are not as yet in a position to accept it as a whole without further investigation.

In the present paper I have endeavored with this classification as a basis to study a series of vasomotor disturbances occurring in private practice and in the Throat Department of the Massachusetts General Hospital.

#### I. INHALATION ANAPHYLAXIS.

Under this heading two main types are recognizable, the first being seasonal, the second perennial. In the first instance we find that the symptoms appear at a definite time of the year, and are represented by the very large class of hay-fever patients, the symptoms coinciding with the flowering of the special plant in question. The second, or perennial form, occurs at any time of year whenever the exciting proteid enters the system through the respiratory tract, as in sneezing or asthma from the presence of horses and cats.

#### IA. SEASONAL INHALATION ANAPHYLAXIS OR HAY-FEVER.

In this affection recognition of the causative agent is considerably simplified by keeping in mind the following facts: In the first place our search should be chiefly directed to the monoecious or dioecious plants. As I have previously pointed out, it is those plants which distribute a large amount of pollen in the air which excite hay-fever symptoms. Entomophilous plants, which accomplish cross fertilization through the agency of insects, are able to be much more economical in the production of pollen, and it is

consequently not likely that such pollen can come in contact with exposed mucous surfaces under natural conditions. Such pollen, furthermore, is more viscid and sticky, the object evidently being to enable it to cling to the bodies of the insects which visit the plant in question. It is necessary, on the other hand, for anemophilous plants, which depend for their fertilization upon the agency of air currents, to produce a large amount of pollen, and pollen, furthermore, which is relatively light, and easily detached from the anthers.

Recognition of these facts enables us to determine with much more certainty the causes of hay-fever in a given locality. We may, therefore, pass over the entomophilous plants and confine our attention to the anemophilous representatives. Such are, in this vicinity, certain trees, especially maples and oaks, the grass family as a whole, and certain species of the wormwood family. Although the pines and other gymnosperms produce a very large amount of pollen, yet I have not so far found any instance of hay-fever being caused by them. It is in the next place necessary to consider the season of hay-fever symptoms. If they occur previous to the flowering of the grasses, we shall obviously have to look for the exciting cause in the early flowering shrubs and trees, and among these birch, maple and willow are chiefly responsible. About the middle or the last of May the oak begins to flower in this region, and tests should therefore be made for this family. The flowering period of these trees is relatively brief, and consequently the hay-fever occasioned by them is less likely to disturb seriously the patient's mode of life.

In the case of grasses we have a flowering period extending from the middle of May in this locality until the first week in July, and the attack of hay-fever which they may excite is not only more prolonged, but more severe.

Examination of the Compositae is very much simplified by recognizing that the proteid or active agent of all its members is essentially the same. While minor differences may exist, yet one active pollen will, for diagnostic purposes, cover the whole order. An interesting example of this is found in two of my patients who spend the winter in Cuba, and who there in February suffer severely from a plant known locally as *Eseoba amarga*, used by the natives to keep fleas from their dwellings, which has been identified for me by Professor Oakes Ames as *Parthenium hysterophorus* Linn. After the return of these patients to Boston in the early spring, they are free from hay-fever until the flowering of the grasses, when a moderately severe amount of vasomotor irritation appears and lasts until the first of July. They then remain comfortable until the middle of August, when severe hay-fever appears and lasts until frost. Examination shows that these patients are sensitized to grasses and to ragweed, and that the Cuban

plant excites marked skin reaction. Tests of this plant on numerous other sufferers from ragweed, who have never been in Cuba, excite marked skin reaction in all cases.

Tests, furthermore, of different members of the Compositae, from the earliest flowering ones, such as coltsfoot, to the late blooming asters, show that with sufficiently strong solutions all ragweed cases will develop skin reactions. Under natural conditions, however, throughout the greater part of the United States, the chief exciting cause among the Compositae is found in the ragweed, the structure of which will repay examination. It will be seen that the plant is characterized by the possession of long spikes containing the male flowers, and by the localization of the female flowers at the base of the spikes. The amount of pollen which this plant distributes is very large, and it is also extremely light. The flowers open in succession, beginning with the central spike, a few discharging daily, and the scattering of the pollen being consequently maintained for a long period. Another plant of the Compositae which resembles the ragweed in its method of flowering is the *Baccharis halimifolia*, a favorite plant in shrubberies, although its power of causing hay-fever has not hitherto been recorded. The plants are dioecious, and the amount of pollen formed is considerable. The more showy members of the Compositae such as field daisy, golden rod, asters and other garden representatives, possess a relatively small amount of pollen, as well as one of a more generally viscid character. Patients consequently more readily escape, unless the plants are brought into the house.

Examination of the present series of cases has led to the conclusion that the number of proteid types concerned in exciting symptoms is much smaller, at least for New England, than has previously been supposed. During the period preceding the flowering of the grasses, nine cases presented symptoms which terminated by the first or the middle of May, according to the seasons. These patients showed no sensitization to grasses, but reacted chiefly to the maple, birch and willow. Fifty-seven cases showed sensitization to grasses, and 183 were positive to ragweed, and other members of the Compositae. Sensitization to members of the rose family alone was found in but one case, although a number were found in association with grass sensitization, where it was evident that grasses were the predominating factor.

With regard to the July or midseason forms of hay-fever, I believe that, with exception of the chestnut and possibly some garden flowers, the chief causes are found either in some special distribution or exposure to either late blooming grasses or early blooming Compositae.

It is at this season also that the cases of olfactory vasomotor rhinitis or pseudo-hay-fever are most commonly found. In this affection the

fragrance of certain heavily scented flowers excites vasomotor disturbances, ranging all the way from sneezing to actual asthmatic paroxysms. The action of pollen can be definitely excluded by wetting or removing the anthers without influencing the vasomotor symptoms. Skin tests, furthermore, of the pollen show no reaction. The phenomena are plainly reflex, and the path of transmission appears to be along the olfactory rather than the optic nerve. The flowers most commonly responsible are lilies, hyacinths, sweet peas and peonies. The condition occurs either alone, or in association with true hay-fever, and is more common in neurotic or impressionable individuals, although not confined to such, several of my cases occurring in highly intelligent individuals, possessing no discoverable neurosis.

It may here be noted that during the hay-fever attack a general hypersensitiveness of the patient is apt to appear toward plants, for which at other seasons he shows only a minor or no reaction. One must therefore be on his guard at this time to observe carefully the relative preponderance or degree of development of the various skin reactions, and he will probably be safe in confining his therapeutic endeavors to the plant which causes the most marked disturbance.

#### II. PERENNIAL INHALATION ANAPHYLAXIS.

(a) Of Plant Origin. Under this heading I have included those cases of vasomotor disturbance in which the exciting proteid is derived from some other part of the plant than the pollen. Two cases of severe sensitization to flour were found in bakers, who, however, had no hay-fever, and who did not react to wheat or grass pollen. These cases, furthermore, could eat bread without disturbance. One case of sensitization to potato was found in a cook. Eight cases of severe sneezing from orris root were encountered in women using face powder containing this as an ingredient. Both the crude root of *Iris Florentina* and the commercially prepared orris powder produced in these cases marked skin reactions and vasomotor disturbances. In several of these patients the cause of the symptoms had not been previously suspected, but in all instances a complete subsidence followed the discontinuance of the face powder.

(b) Of Animal Origin. Forty-nine cases were found of sensitization to epidermal scales and hairs of animals or feathers of birds. The symptoms varied from vasomotor rhinitis to severe asthma when inhaling fine suspended particles of the special exciting substance in question. In all cases a definite reaction was elicited by the application of a keratin extract to a scratch of the skin. While the majority were aware of their sensitization, yet for a number of individuals the first recognition of the

cause was obtained by the test. This was especially found in the case of children.

Of the various animals, the horse was represented by forty-two cases, the dog by eight, and the cat by six. The sheep and cow gave in two cases respectively moderate but apparently definite reaction to keratin extracts from the natural hair, but it did not appear that the first case was affected by the dust from woolen blankets. In two cases definite vasomotor rhinitis was occasioned by the use of feather pillows, and keratin extracts from feathers of the chicken or duck gave well-defined skin reactions. The symptoms disappeared on the discontinuance of the feather pillow.

A distinct difference appears to exist between the proteid of the serum and that of the epidermal structures in the animals studied. In the case of the horse eleven patients gave marked reactions to the keratin extract but no reaction to the serum either in pure powder or as antitoxine. That this difference is not due to greater strength of the keratin extract employed is shown both by the fact that the majority of patients gave equally marked reactions to both serum and keratin, and by the observation made in one individual of a pronounced cutaneous reaction to horse serum, without a trace of disturbance from the keratin. This patient had had but little to do with horses, but had, thirty-eight years previously, been bitten by a colt. It is conceivable that in this manner a sensitization to the serum alone may have developed.

While the majority of the dog and cat cases reacted to keratin, both clinically and by the tests, yet two individuals were discovered who reacted to dog serum in a marked degree without sensitization to dog hair. Two similar cases were found reacting to cat serum alone. These four individuals had no discomfort when in the neighborhood of dogs or cats respectively.

Of the two cases of feather sensitization, one showed no reaction to eggs.

These observations indicate the necessity of employing keratin extracts as well as sera, when making diagnostic tests of sensitization. Furthermore, the probability is suggested that certain cases of horse-fever or horse asthma may in reality receive antitoxine without anaphylactic shock, if their sensitization is to the hair and not to the serum of the animal. Finally, the possibility is conversely suggested that the absence of symptoms from horses does not preclude the possibility of an anaphylactic shock from the administration of antitoxine.

## II. INGESTION ANAPHYLAXIS.

Twenty-eight cases were characterized by a more or less well-defined sensitization to various foods. This number does not represent the true relative frequency of such cases, since their study has been undertaken only during the

past six months, and many of the earlier ones may have escaped recognition.

These cases represent all gradations ranging between sensitizations so slight as to have excited no subjective symptoms on the part of the patient and extreme susceptibility in which contact of the smallest part of the proteid in question caused profound general disturbance. It was noted that the local sensations were referred to the throat, rather than to the region of the stomach. Such symptoms were described variously as tickling or itching in the throat, or, in more severe cases, as swelling and smarting. The general constitutional phenomena were in some cases definite asthmatic symptoms, in others urticaria. Eczema was found associated in a number of instances; psoriasis occurred once.

Animal foods were prepared for testing, as already described, and instances were found of sensitization to shell-fish, crustacea, fish of various sorts, egg, milk and meat. If the skin reaction was marked, the patients were usually aware of their idiosyncrasy. This applies particularly to intolerance to fish and eggs.

Milk was found in one instance to give severe asthma in a child seven years of age. This patient had had more or less constant asthma since being weaned. Physical examination by Dr. J. L. Morse was negative. The skin tests showed reaction to milk, horse and cat keratin. On discontinuing the milk, and keeping the cat away, the asthma ceased completely. At the end of two weeks the child was given cow's milk again, with a return of the asthmatic symptoms. This was allowed to continue for a week, and the milk discontinued, the asthma simultaneously disappearing. A week later he was allowed to play with the cat, whereupon asthma reappeared. On keeping him away from the cat, and giving milk at the beginning in drop doses, and gradually increasing, it was possible at the end of six months to establish a tolerance for a glass of milk. The child has during this time been free from asthma.

Cases of sensitization to egg have been referred to children's specialists for immunization by progressive doses, with successful results.

A case of sensitization to raw animal sera was found in a boy twelve years of age. This individual reacted to dog, cat, hog, sheep and ox serum, to a high degree. Horse serum and goat serum excited slight reaction. Guinea-pig serum gave no reaction. Tests with cooked beef and lamb gave no reaction. There was well-defined sensitization to keratin of dog, cat, horse and lamb, but none to that of the ox. Commercial casein and egg gave no reaction. This case indicates the desirability of having the animal foods prepared for testing under the form in which they are usually taken into the system.

In the case of plant foods we have likewise to prepare the material in the raw, boiled or roasted state, as the case may be. A variety of

proteid substances exists in plants, the greater part of which is coagulable by heat. While many proteid substances in aqueous solution require a temperature of 100° C. before being coagulated, others coagulate at 65° C. Proteoses withstand boiling, but may be precipitated by treatment with absolute alcohol. Eleven cases were found of sensitization to grains. In certain of these the patients had no subjective sensations. In four, however, it seemed probable that the asthmatic symptoms of which they complained were attributable to the eating of grains in the form of cereals and bread. Two of these cases are reported somewhat in detail.

CASE 1. G., 40. Asthma, since childhood, of unknown origin, more or less persistent throughout the year. No reactions were found to animal foods or to the pollen of grasses, and the patient had no hay-fever. Raw and boiled proteids of wheat, barley, oat, corn and rice gave marked skin reactions. Proteids extracted from the inside of bread gave reactions much less pronounced than the raw or the boiled material. Extracts prepared from well-browned toast and some roasted grains of wheat, corn and rice gave no reaction whatever. Various breakfast foods were tested, shredded wheat, triscuit, corn flakes, force, Kellogg's wheat biscuit and puffed rice giving no skin reaction. Grapenuts gave a pronounced reaction. The patient was negative for other plant foods with the exception of beans and peas. Bread and boiled cereals were omitted from his diet for a period of two weeks, during which time his asthma became much less, giving him at the close of this time practically no discomfort except on exertion. On eating again freely of bread, after two days the asthma returned in its original intensity, diminishing later when bread was omitted. When the roasted cereal foods above mentioned, which gave negative reactions, were introduced into the diet, there was no return of the asthmatic symptoms, and the patient is now in greatly improved general health.

CASE 2. S., 35. Asthma many years more or less constant. Hay-fever in spring, moderate. Marked reaction to wheat, raw and boiled, and to bread proteid. Marked reactions to raw and boiled proteids of oat, barley, rice and corn. Positive reactions were obtained also for cocoa and buckwheat. Squash, pea, almond, and Brazil-nut gave pronounced reactions. There was no reaction to beet, turnip, cabbage, parsnip, potato, eggs, fish or meat. This case was relieved very much of his asthma on omitting bread and grains, and the other plant foods to which he was sensitized. A proteid extract of wheat was treated with pancreatin for three days. This modified extract caused marked skin reactions. Wheat, rice and corn, heated to a temperature of 115° C., gave no reaction, and their proteids on treatment with pancreatin for three days gave no reaction.

These two cases indicate that certain proteids present in the grains are heat stable up to 100° C., but at 115° C. their anaphylactogenic property is destroyed, and is not reintroduced by pancreatic digestion.

Four cases of sensitization to potato, both raw

and boiled, were observed. In one of these only was there any systemic disturbance, this consisting in an urticarial eruption. Proteids from baked potatoes gave no skin reaction.

Cases were also encountered of sensitization to nuts, both walnuts, chestnuts, and Brazil nuts, some reacting also to almond, although this is derived from the rose family, and stands far removed in a botanical classification from the others. These cases did not react to the pollen of chestnut or the rose family, respectively. A few cases were found of sensitization to strawberries, bananas, oranges and apples in the raw state. Cooking, however, of the strawberries and apples made it possible for the patients to eat the fruits without discomfort. The inference here to be drawn is that the sensitizing proteid was coagulated or destroyed on boiling. The cases of clinical sensitization to grains as a rule had no hay-fever, and did not react to the pollen of grasses. It was, however, observed that cases of marked sensitization to grass pollen gave without exception a definite skin reaction to proteids, both boiled and raw, of grains. This observation suggests the probability that the pollen represents the specific plant proteid found throughout all its parts, as Metz and Gohlke have apparently shown, but that in the development of the ovule during the summer other proteids are formed with anaphylactogenic properties differing from those of the specific plant proteid, and that these seed and fruit proteids represent a high degree of differentiation among closely related species. This clinical observation receives confirmation from the works of Wells and Osborne.

These observers have isolated from the seeds of closely allied plants substances resembling proteoses, which are distinguishable from each other. They reach the conclusion that resemblances and differences of these substances are dependent upon the chemical constitution of the proteid molecule, rather than upon biological differences. They, for instance, found that zein, the alcohol soluble protein of corn, did not cause the anaphylactic reaction in animals sensitized with gliadin, the alcohol soluble proteid of wheat, nor with hordein, the alcohol soluble protein of barley. At that time hordein and gliadin had not been tested against one another, but it had been observed that preparations of gliadin from either wheat or rye interacted against one another, as if they were one and the same protein. On testing hordein from barley against gliadin from either wheat or rye, they have since found that these two proteins of different origin also react with one another. Furthermore, they have found, that while preparations of gliadin from wheat reacted anaphylactically with glutenin from the same seed, hordein from barley fails to cause reactions in guinea-pigs sensitized with glutenin.

It has seemed to me possible that these relationships between the specific plant proteid

found in the pollen, and those of the seeds and fruits may be represented graphically as follows: Taking, for instance, the Rosaceae, we may let A represent the specific proteid of the family found in the pollen and throughout all the parts of the plant. B, C and D may be taken to denote the fruit proteids of the apple, strawberry and almond, elaborated by the activity of the respective plants during the summer's growth. The proteids present in the fruits will therefore be AB, AC and AD. An individual sensitized to the pollen of the rose will react positively to the pollen of all the members of that order, and will also react to extracts from the fruits or seeds of B. If, however, he is sensitized to proteid B of the apple, he will react neither to the pollen of any of the rose family nor to proteid C of the strawberry nor to proteid D of the almond.

This hypothesis has apparently received confirmation from my observations on the Rosaceae and Gramineae, as already mentioned.

### III. AUTOLYSIS OF BACTERIAL PROTEIDS.

While the influence of proteids from animals and from flowering plants in the causation of anaphylactic symptoms is sufficiently recognized, yet the part which possibly bacterial proteids may play in these conditions is not yet clear. Clinically we find a large number of cases in which the influence of bacteria seems probable. We may divide these conditions provisionally into acute recurrent and chronic forms. In the first instance we find that the individual goes for considerable periods of time with little or no vasomotor disturbance, and that with the advent of an acute infection of the nasal or bronchial mucous membrane, he exhibits symptoms of vasomotor rhinitis or of asthma. The mucous membranes in these conditions do not show reddening or pus formation which are characteristic of acute rhinitis and acute bronchitis, but present rather the typical picture of hay-fever. After the cessation of the acute symptoms, the individual is free from asthma until the occurrence of another infection. The existence of chronic forms of bacterial infection have been recognized by clinicians as being represented on the one hand by chronic sinusitis and on the other by intestinal stasis, and we have probably all had cases where treatment or cure of these conditions has resulted in relieving the vasomotor symptoms. I believe that chronic lacunar tonsillitis with accumulation of detritus must be regarded also as a possible cause of proteid absorption.

In a recent paper<sup>1</sup> I have called attention to the possible explanation of such types of vasomotor disturbance, referring them to the solution or autolysis of bacterial proteids, to which the patient is sensitized. On this hypothesis both these acute and chronic forms of vasomotor rhinitis and asthma are dependent upon the occasional or constant anaphylactogenic action of

autolyzed bacteria. Experiments which were then reported for the purpose of determining whether bacterial proteids in solution could elicit skin reaction, showed that out of fifty cases positive reactions were obtained from the staphylococcus p. albus, aureus and citreus; also from a bacillus of the Friedlander type, and the micrococcus tetragenus. Since then further study has confirmed these observations, and reactions have been obtained in a number of cases from the bacillus of influenza, streptococcus pyogenes and viridans and the pneumococcus, Types I and II. It was also observed that after an attack of asthma the skin reaction could not be elicited, but returned again after a few weeks. Much still remains to be done before conclusions can be drawn as to the relation of these organisms to the vasomotor disturbance in question. If it should be confirmed that definite sensitizations to microorganisms exist on the part of these anaphylactic cases, our therapeutic work should receive a highly important assistance. We should, for instance, in the case of acute recurrent infections, be guided in the choice and administration of vaccines. The cases of chronic proteid absorption would be more intelligently approached in that we should be led to examine the patient with especial care for the purpose of removing, if possible, the foci of infection, or at least of draining and cleansing the regions in which prolonged contact of bacterial proteids may occur.

### ASSOCIATION OF FACTORS AND THE OCCURRENCE OF CLINICAL SYMPTOMS.

A review of the cases has shown that for the majority a variety of sensitizations is present. We find, for instance, often hay-fever disturbances from the pollen of different orders, while here and there hay-fever patients occur with sensitization also to bacterial proteids, certain classes of foods, or keratin desquamations.

In such cases our task is first to determine the factor which is responsible for the symptoms, and to place in proper perspective the relative influence of the other sensitizations to which the patient is subject. The line of inquiry is usually as follows: First, Are the symptoms strictly seasonal? In this case we shall obviously be able to disregard all factors except the various pollens. If the symptoms are perennial, inquiry is next made as to their relation to the occurrence of colds and acute infections. If the answer is confirmative and the patient states he is entirely free from discomfort except when suffering from a cold or acute bronchitis, we may feel justified in disregarding the influence of both inhaled and ingested proteids, and devote our attention to an examination of his reactions to the various bacteria concerned in acute infections of the upper air passages.

If the symptoms are more or less constant throughout the year, the possible influence of

domestic animals should be sought for, especially dogs and cats in the case of children. Nor must the possibility of orris root in toilet or sachet powder be forgotten. Inquiry is next made as to disturbance from different articles of foods, and here the tests should be first made for such substances as enter habitually into the diet. Thus, in order of importance, we place eggs, milk, meat, grains, legumes and potatoes, since if the patient is not sensitized to any of these, it is unlikely that the more occasional articles of diet, such as shell-fish, fish, root vegetables, greens and fruits are responsible.

If the above tests have resulted negatively, our attention should be directed to the possible existence of chronic absorption of bacterial proteids, and we may then proceed with the examination of the patient, as to his sinuses, tonsils and gastro-intestinal tract.

#### THE MANAGEMENT OF PATIENTS SHOWING HYPER-SUSCEPTIBILITY.

In symptoms arising from inhalation of sensitizing substances, if the exposure is likely to continue throughout the year, it is probably wiser to avoid the irritation than to seek to immunize the patient against it. We have at least as yet no record of successful immunization. A case which I reported last year of attempted immunization against horse asthma by the injection of horse serum and keratin extract showed a gain in tolerance to the presence of horses, but on the discontinuation of the treatment, the immunity was gradually lost, and the patient has now regained her original sensitiveness. Since for the successful preservation of the acquired resistance continuation of proteid administration is necessary, and inasmuch as we have yet developed no successful method which the patients would be willing to carry out for an indefinite period, it would seem preferable for the patient to accept his disability, and make the best of it.

Immunization against hay-fever by the injection of plant proteids has been described by other writers, and by myself in a previous paper, so that I shall not consider it here in detail. Before, however, we undertake the treatment, we should first decide whether the patient's discomfort is sufficient to justify us in starting him upon a course of procedure which may prove time-consuming and not wholly devoid of risk. The treatment is by no means to be compared to typhoid inoculation, but will require numerous visits with careful tests of the degree of progress in order to determine the correct dose for each occasion. I cannot too strongly emphasize the importance of this matter of dosage. We are dealing with agents capable in moderate overdose of causing unpleasant shock, and in sufficient amount, of leading promptly to a fatal result. The best advice that I can give one starting in this work is to test continually the patient's resistance, and to increase

the doses gradually in conformity with the skin or conjunctival tests.

In reviewing the results thus far obtained in three years' treatment of hay-fever by hypodermic injection, one must in the first place be guarded in accepting the statements of the patients themselves. As I have previously pointed out,<sup>7</sup> seasons vary, and the physical condition of the patient may, likewise, differ from year to year. Patients are all too ready to attribute a greater freedom from hay-fever symptoms to the treatment employed. It is only where the patient's statements are controlled by clinical tests that they may be accepted as possessing value. With this preliminary statement I will say that the majority of patients who received treatment in the past two summers expressed themselves as satisfied with the results accomplished. From those who felt themselves improved, however, a considerable number should be eliminated, as careful examination of their surroundings, the season and their physical condition might permit other explanations of the diminution in symptoms. The typical individual who presented himself for treatment two or three months before the expected season showed a progressive diminution in the intensity of the skin reactions, and a greater tolerance to the solution employed. In most instances, however, the patients did not escape entirely the hay-fever symptoms when the season came around. The typical behavior was as follows: Hay-fever appeared at the usual time or somewhat later, the latter possibly attributable to the season, and reached within a few days nearly its accustomed degree of intensity. This was, however, followed by a striking diminution in the symptoms, so that after the acme of discomfort had been reached, a very considerable degree of relief supervened, and most of these cases remained relatively or entirely free from trouble through the balance of the season. The impression was given in such cases that the amount of treatment which it had been possible to administer in the few weeks before the season was insufficient to effect a complete immunity, but that with the arrival of the season enough pollen was absorbed through the mucous membrane to push the patient, so to speak, over the line. The same results were apparently obtained when treatment was instituted at the beginning of the hay-fever season, and in the majority of such instances it was possible to bring about a relief of hay-fever symptoms several weeks before relief would ordinarily have been due.

I have received the impression consequently that we are not likely in the majority of cases with the present methods to do away completely with hay-fever symptoms in the course of a single season, but that, nevertheless, sufficient relief may be obtained to make it worth while to continue this method.

Where, however, treatment has been carried on during one season with more or less success,

it has been evident that a second course of treatment the following season is more distinctly efficacious.

The usual course of events here is as follows: At the close of the first hay-fever season one finds that the patient has attained a relatively high degree of immunity, which in the course of the winter progressively diminishes. Beginning again next season several weeks before the expected date for hay-fever, one injects a small dose carefully determined in the usual way, and follows this by larger doses. In practically all such cases a rapid striking diminution in the intensity of the skin reaction was observed, much more speedily than was the case during the first season. Such cases when the hay-fever season arrived were distinctly more benefited than during the previous year, more than half showing no or exceedingly trifling symptoms. The work is yet too young to enable us to say with certainty what the future will bring forth, but with our present information I should advise considerable caution in the statements to be made to the patients, and especially to explain to them that they may observe little or no benefit during the first season, but that the results obtained lead us to advise a following out of treatment for two years, with the reasonable expectation that the second season's treatment will be more helpful than the first.

Although feeding experiments in the past with extracts of ragweed do not appear to have been sufficiently successful to justify their general adoption, yet the work which internists have done with the treatment of egg sensitizations, has suggested the possibility that we may accomplish similar results by administering foods in a natural state derived from the order which produced the symptoms. Experiments were consequently undertaken during the past summer to determine whether the patients sensitized to ragweed pollen would present symptoms from the ingestion of proteid foods derived from the same family.

It was thought that if such internal administration was followed by the development of vasomotor symptoms, either of the skin or of the mucous membranes, an immunization might possibly be accomplished along the recognized lines of treating egg and other food sensitizations.

For this purpose sunflower and lettuce were taken, both being plants of the Compositae, to which the ragweed also belongs. The pollen of both was found to excite marked skin reaction in cases of autumnal hay-fever.

Extracts were made from the seeds of the Russian sunflower which gave positive results, but the intensity of the skin reaction was inferior to that excited by the pollen. The seeds were given to ten hay-fever patients with the direction that they should chew them thoroughly and swallow shortly before their regular meals, with the idea that a certain amount of

the proteid might pass into the system directly without digestive alteration. In nine adult cases, however, no gastric discomfort was noted or any influence upon the hay-fever symptoms. Oil-free meal from sunflower seeds was prepared, which on the skin excited a moderate or marked skin reaction, depending upon the sensitization of the individual. This was administered internally in doses of one to two grams, without exciting symptoms of any kind whatever. One patient, a boy, said that his hay-fever was made worse after eating the sunflower seeds.

In the case of lettuce a strong extract was made from the seeds in a 5% sodium chloride solution, which gave a weak reaction. A strong solution of lettuce leaves in a 10% sodium chloride solution (proteins shown to be present by preliminary test) gave a negative reaction.

The amount of proteid present in the lettuce leaf is evidently too small to excite any disturbance, and with one doubtful exception, no patients had noted any influence upon their hay-fever from eating it in abundance.

It would appear consequently probable that we have no foods of the Compositae order, the ingestion of which is likely to influence the course of ragweed hay-fever.

In the course of this work it has become evident that many individuals exist who show definite anaphylactic skin reactions to various classes of foods, and the problem which here confronts us is to determine to what extent the clinical vasomotor symptoms are dependent upon such a hypersusceptibility. It has in some instances seemed indicated that certain individuals possess food sensitizations either partly developed or measurably overcome through the acquisition of progressively increasing tolerance, in whom the actual vasomotor explosion is in reality dependent upon some other proteid cause. The following case illustrates this possibility.

D., male, 40. Asthma severe, nearly constant for many years. Marked polypoid degeneration of middle turbinates with involvement of antra. Skin tests were positive for staphylococcus p. albus and a diphtheroid bacillus; negative for pneumococcus, the influenza bacillus, micrococcus catarrhalis and staphylococcus p. aureus. Positive reactions were obtained from proteid extracts of wheat, barley, corn, rice, pea, orange and cocoa. Negative or slight reactions were obtained from egg, milk, beef, mutton, fish, potato, carrot, beet, parsnip, squash and cabbage. Keratin extracts of domestic animals and birds were negative. The patient was put upon a diet containing only those foods to which he was negative, but without perceptible influence upon the asthma. No operation has as yet been done upon his sinuses, but in view of the above observations this seems the measure most reasonable to undertake.

Conditions of highly developed sensitization to foods have been studied by numerous observ-

ers, especially Schloss, Talbot and Chappell. It has been evident that children are much more prone to exhibit anaphylactic phenomena from foods than is the case in adults,—a fact possibly due to the greater absorptive power of the gastric mucous membrane in children, or to the acquisition of partial immunity in adults.

If the proteid enters into the accepted articles of diet, experiments have shown that immunity can be obtained in the majority of cases by administering it in small and progressively increasing amount. The details of treatment may be found sufficiently described by the authors mentioned.

The management of cases in which the vasomotor symptoms either demonstrably or by exclusion are attributable to the absorption through the mucous membrane of bacterial proteids is to be undertaken along lines already indicated. Aente recurrent infections may perhaps be checked by the administration of vaccines. The sensitized individual presents here an advantage in that it may be found possible to select for him with accuracy the special organism required.

Foci of chronic inflammation or sepsis should be drained or removed. In three of my cases of long-standing asthma, the excision of septic tonsils was followed by entire relief.

Cases of intestinal stasis should be treated by the internist or the orthopedic surgeon, as circumstances may require. Two cases of asthma with ptosis of the viscera were relieved by the application of a proper support.

#### CONCLUSIONS.

In a large proportion of vasomotor diseases of the upper air passages the disturbances are dependent upon the entrance of a foreign proteid into the system. The method of entrance may be through the contact of the proteid in question with mucous membranes of the respiratory or of the gastro-intestinal tract by inhalation or ingestion respectively. Foreign proteids may perhaps also develop in or upon these mucous membranes through autolysis of pathogenic or saprophytic bacteria. The application of the skin test to these conditions is of diagnostic value when employed with a recognition of the phylogenetic relationships of animals and plants, as determined by studies in sero-biology.

Proteid material for testing should be prepared both from the keratin and sera of domestic animals, from the pollen of the chief causes of hay-fever, and from the various articles of food, which enter commonly into the diet. Bacterial proteids derived from the various invaders of the respiratory tract should be available either in solution or in soluble form.

When the skin reactions to the various classes of pollen proteids have been determined, the management of cases will depend largely upon the relative preponderance of the local reactions

in relation to the clinical history. If the cause is found to be seasonal, as in hay-fever, immunizing treatment by injection of pollen extracts is likely to prove of service. The sensitization returns during the following winter, and treatment must probably be repeated annually. If the cause is perennial and is due to inhalation of foreign proteids, it is wiser to avoid the cause rather than to seek to effect a cure by immunization. If the disturbing proteid enters into the ordinary articles of diet, a tolerance may be gradually established by feeding the substance in progressively increasing doses. Disturbances of bacterial origin have not yet been sufficiently studied to enable the formulation of a definite plan of treatment; but the results of these investigations confirm our present methods of treatment, and emphasize the importance of draining regions which can retain the products of bacterial activity. Septic foci should be removed. Vaccine therapy is likely in such anaphylactic cases to be more accurately guided than in the ordinary individual.

The results already accomplished in the case of this clinical investigation has led me to the conclusion that we possess in the intelligent application of the skin test a very definite aid in the diagnosis and consequent management of our cases of vasomotor disturbances of the upper air passages. We are as yet only at the entrance of this field, and its exploration must be carried out by the coöperation of laboratory workers in chemistry and serobiology.

## ASTHMA IN CHILDREN, II. ITS RELATION TO ANAPHYLAXIS.

By FRITZ B. TALBOT, M.D., BOSTON.

Chief of the Children's Medical Department of the Massachusetts General Hospital; Instructor of Pediatrics, Harvard Medical School.

IN 1914 the writer reported six cases of asthma in children due to eggs.<sup>1</sup> Later, more careful review of the literature showed that Meltzer<sup>2</sup> was one of the earliest investigators to attribute the symptoms of asthma to anaphylaxis, on the basis of observations he had made on animals. Koessler<sup>3</sup> (1913) and Lesné and Richet<sup>4</sup> (1913) reported cases of asthma in young children caused by eggs. Richet<sup>5</sup> noted that cooking diminishes, but does not always remove, the toxicity of eggs. Recently opportunity has been afforded to study a series of cases

which have modified and broadened the conception of the etiological factors concerned in the production of asthma, and much more delicate materials have been used in the tests.

The histories of most of the cases studied have shown that there is a hereditary predisposition to allergy; that the parents or close relatives of the children have asthma, hay fever, or an idiosyncrasy to some food. During the year of 1914-15 the writer made a routine skin test for egg albumen on all the children and infants admitted to the Children's Ward at the Massachusetts General Hospital, and out of 85 admissions, three infants gave a positive skin test to egg albumen. They were respectively, three, four and eight months of age. The mothers of the infants, on being carefully questioned, said that the babies had never eaten egg in any form. A fourth case, in private practice, aged fourteen months, which had never eaten egg, gave a positive skin test to egg white. Schloss and Worthen<sup>6</sup> report the same results in two infants, and Blackfan<sup>7</sup> in one nine weeks old infant. It seems certain, therefore, that these infants had a hereditary and not an acquired sensitization to egg.

Sensitization may be acquired. It has been shown that the intestinal mucous membrane of the new-born infant is permeable to foreign protein for a short time after birth, and that later the foreign protein will not pass through the mucous membrane into the blood (when given in normal amounts), unless the mucous membrane is damaged.<sup>8</sup> Recently Schloss and Worthen<sup>6</sup> showed that whereas the healthy digestive canal of infants could take care of a small amount of foreign albumen (in this instance, egg albumen), large amounts passed through the intestinal mucous membrane unchanged, and could be demonstrated in both the blood and the urine. This investigation is of great importance since it explains many phases of asthma for which no satisfactory explanation could be given. Graphically it may be shown as follows:

A-A The limit of tolerance to foreign protein.

B-B Increasing amounts of foreign protein.

C-C To immunity.

Diagram of theoretical action of foreign protein in a sensitive case.

Any amount of the foreign protein below the line A-A, which represents the limit of tolerance, will be digested and changed so that none enters the body, while any greater amount will gain entrance to the body through the intestinal mucous membrane. Let the line B-B represent increasing amounts of foreign protein (for example, egg albumen). When the line B-B passes above the line A-A, the amount of protein given is greater than can be tolerated, and presumably passes into the body unchanged. One of two things results,—either the limit of tolerance is increased and immunity is established for that amount, as shown by diverting line A up the dotted line C-C, or some symptoms appear, which make it impossible to continue with such large amounts of the foreign protein.

During the past two and a half years a series of investigations, especially by Goodale<sup>9</sup> and Walker,<sup>10</sup> have made it possible to divide asthma and the allied condition, hay fever, etiologically into three types.\*

Inspired	Hay fever—pollens <sup>10</sup>	
	Dust and hairs from animals <sup>9, 12</sup>	Horse Cat Dog Guinea-pig, etc.
	(a) animal foods, egg, beef juice, etc.	
	(b) vegetables, oatmeal, lentils, etc.	
Ingested foods	(c) milk	
	(d) fruits	
	(e) nuts	
	(f) fish and shell fish	
Bacterial <sup>10</sup>		

The problem in children is quite different from that in adults, since during the first year of life sensitization to the foods alone is seen. The youngest recorded cases of asthma are respectively fourteen and twenty-eight days old.<sup>13</sup> As the child grows older, inspired asthma becomes more frequent, with increasing exposure to pollens and dusts, but this type is only a small proportion of the whole. A larger proportion of cases are still due to foods, and for that reason the writer's investigations have been confined almost wholly to the foodstuffs.

Since food idiosyncrasies and allergy, with resulting asthma, tend to cure themselves spontaneously in childhood, the proportion of cases of asthma due to ingested foods becomes smaller with increasing age, while the proportion of those due to inspired materials become larger. In later childhood and adult life there were many puzzling cases which were unexplainable until Goodale showed that asthmatics may give a positive skin test to bacteria, which presumably explains this group of cases. As the child becomes older it contracts infectious diseases, which, on proper soil, may be so spaced in time as to cause the patient to become allergic. The bacterial type of asthma is relatively rare in

\* The writer reiterates here what he said in the first paper on Asthma in Children, viz., that only those cases are asthma in which renal, cardiac, thymic asthma, and asthma due to enlargement of the bronchial glands have been excluded.

childhood (the writer's tests so far have all been negative), and more common in the adult.

There is yet another group of cases which give negative skin tests, and in which no etiological cause for the asthma can be found. The explanation may be that either the materials used in the tests were not concentrated or strong enough, or the proper materials were not selected, or that there is still another type of asthma.

The writer has followed forty-five cases of asthma in childhood over a period of several years. Five of these cases gave a history of egg idiosyncrasy, but have outgrown the idiosyncrasy and asthma without treatment, and are thus consistent with the general opinion in text-books, that children are apt to outgrow asthma.

During the course of the past three years the methods of determining the etiological cause of asthma have improved both in the technique and in the materials used in the tests. The skin test is performed as follows: A linear scarification is made about one-half an inch long, and only deep enough to penetrate the outer layers of the skin, care being taken not to draw the blood. In each case an extra scarification is made as a control, because it is a well-established fact that the mechanical injury to the skin may result in a pseudo-reaction (an elevated white area surrounded by a small roseola), especially in patients with an "exudative diathesis."<sup>14</sup> The scarifications† are then inoculated by placing the materials to be tested (preferably in fresh solution) on the scarifications, and watching them for twenty minutes. A positive reaction appears in from two to ten minutes, and in rare instances a delayed reaction is seen in one to two hours. A positive reaction gives an urticarial wheal with an irregular outline surrounded by a pink blush, both of these phenomena being absent in the control. In some cases the blush, without the urticarial wheal, is so pronounced that there is no question that there is a positive reaction. Itching may or may not be present. The reaction usually disappears within one-half to two hours. The more delicate the skin the more sensitive it is to a foreign protein, and the more readily will it react even when it is unbroken or only slightly broken. The skin of an infant reacts very readily, and even when healthy is capable of absorbing the foreign protein in some instances. When the skin becomes thicker and hardened by exposure, as in the male adult, it reacts less readily, requires a more concentrated test solution, and a deeper scarification. Children and young women with delicate skins react almost as easily as do infants. The skin of the inner

flexor surface of the arm is thinner and more sensitive than that of the outer arm, and for that reason is the best place to make the scarifications.

The materials used in the skin tests were at first watery extracts of cereals, and expressed juices (whenever they could be obtained), and were prepared freshly in the office. Later the pure proteins of various vegetables, fruits, and nuts were prepared by Mr. Wodehouse working in the Botanic Garden at Harvard College, and found to be more satisfactory than the home-made product. They contain a more concentrated solution and do not deteriorate. Naturally, the scope of this investigation increased with the number of materials which could be tested, and the thoroughness with which the cases were studied increased with the materials prepared for the tests.

Of the 45 cases in this series there were thirteen in which the skin tests gave no clue to the etiological cause of the asthma. They were either not tested with the proper material or they were anti-anaphylactic.<sup>15</sup> The difficulty of finding the cause of the asthma is shown by a case in which 38 tests were made before positive information was obtained.

Twenty-three cases of the series have been carefully studied, and of these 18 had eczema at some time or other. This is a higher proportion than that reported by Berkhard,<sup>16</sup> who found that in 117 cases, 44 had eczema simultaneously. A family history of asthma, hay fever, rose colds, eczema, or idiosyncrasy to some food was present in 19 out of the 23 cases, while in the remaining four cases there were no notes, in the family history, on these points. Berkhard also found a "hereditary element" strongly marked in 16% of his cases. It seems, therefore, that there is a strong family predisposition to asthma.

In 19 of the 23 cases selected from this series there was a positive skin test to fresh egg albumen.

Out of the total 45 cases the following positive skin tests were obtained:

Eggs .....	27
Beef juice.....	5
Rice flour (crude) (a).....	2
Oatmeal flour (crude) (a).....	2
Green pea (crude) (a).....	1
Kidney bean (crude) (a).....	1
Lima bean (crude) (a).....	1
Black bean (crude) (a).....	1
California pea bean (crude) (a).....	1

Watery extract of orange (b).....	1
Almond protein (b).....	2
Almond (crude) (a).....	4
Brazil nut protein (b).....	2
Brazil nut (crude) (a).....	3
Walnut protein (b).....	3
Walnut (crude) (a).....	5

† There is still some doubt as to whether the scarification or the intracutaneous test is the best. There are two points in favor of the use of the scarification test,—its simplicity and the difficulty of interpreting the intracutaneous reactions in some instances. It is probable that the intracutaneous test is the more delicate, as shown by Blackfan. The writer's experiences do not justify the conclusions of Stickler and Goldberg (*Jour. Amer. Med. Assn.*, 1916, lxxvi, 246), who considered the reactions positive only when the erythema persisted for 48 hours.

Pean (crude).....	3

(a) Crude in this table means that the fresh flour was dissolved as much as possible in cold sterile water or normal salt solution and applied without filtering.

(b) Protein = the protein supplied by Mr. Wodehouse.

(c) In the crude preparation of nuts, the nut was broken, squeezed and some of the expressed fluid placed on the scarification.

\* Pinus ebulis imported from the southern coast of Italy.

It was found that one individual was apt to react to more than one form of protein, as shown in the case of a child who reacted to egg, lima beans, rice, green split pea, protoid nut, whole wheat, kidney bean, and California pea bean.

The frequency of positive reactions is illustrated by the following figures:

- 6 cases gave only 1 positive skin reaction to different materials.
- 4 cases gave only 2 positive skin reactions to different materials.
- 1 case gave only 3 positive skin reactions to different materials.
- 5 cases gave only 4 positive skin reactions to different materials.
- 2 cases gave only 5 positive skin reactions to different materials.
- 1 case gave only 7 positive skin reactions to different materials.
- 2 cases gave only 8 positive skin reactions to different materials.
- 1 case gave only 9 positive skin reactions to different materials.
- 1 case gave only 10 positive skin reactions to different materials.

It is still too early to say whether all of the positive reactions are of equal clinical importance, but experience seems to show that the severity of the symptoms is not always indicated by the size and character of the reaction. If an individual reacts to one kind of nut he probably will give a skin test to all nuts, except the roasted peanut,\* which is a lentil. It has been found, however, that the severity of the reaction may vary, as, for example, one case which had a marked reaction to the protein of the almond and only a moderate reaction to that of the walnut and Brazil nut. This difference in the reaction may be explained by the difference in the family of the nut. In the same manner, an individual who reacts to the egg of the hen also reacts to the egg of the duck, turkey, buff cochin bantam, English pheasant, pearl guinea hen, Japanese silkie and pigeon. The reaction is, therefore, to the egg and not to the species of the bird. The yolk and the white

\* The heat of roasting the peanut may make it suitable for sensitive individuals.

of the egg each react, but the white usually reacts more strongly than the yolk.

Experience has shown that when a positive skin test is obtained for a food, and the food is then removed from the diet, the general condition of the patient almost invariably improves, and in many instances a cure results. In other instances it is necessary to induce an artificial immunity because of the difficulty in entirely eliminating the offending protein from the diet, as, for example, eggs or milk. Immunity may be induced in these patients by giving increasing doses of the offending protein as described by Schloss.<sup>17</sup>

#### CONCLUSION.

A definite etiological connection may be established between most cases of asthma and some foreign protein by the skin test. If an individual is sensitive to one protein he is also apt to be sensitive to other proteins. The large number of cases with family histories of asthma or food idiosyncrasies makes it seem probable that there is a hereditary predisposition to sensitization. Information given by the skin test is of inestimable value in outlining the treatment of the case, and with the use of this information, marked improvement or cure often follows. Further study will undoubtedly add much to our knowledge of asthma and its allied diseases and will still further modify our conception of the processes involved.

## PREPARATION OF VEGETABLE FOOD PROTEINS FOR ANAPHYLACTIC TESTS.

By R. P. WODEHOUSE, CAMBRIDGE, MASS.

[From the Laboratory of Plant Physiology, Harvard University.]

IN studying the sensitization to various food proteins which results in asthma, eczema, etc., investigators have for the most part used a watery extract or the foods themselves to make the tests. This method, besides being clumsy, has obvious disadvantages, for it is desirable that the proteins of the vegetable foods to be studied should be as concentrated and in a form as easily handled as possible. Chappell ('15), in his studies on asthma, used concentrated extracts of strawberries and tomatoes, prepared by precipitating the watery extract with alcohol, for making the tests.

In the winter of 1915 the writer, without attempting to find out exactly which proteins in the foods were responsible for the biological reactions, endeavored to find a method of concentrating them all together in such a form that they would keep and be easily available for making tests.

It was found that an extract made with pure water would give just as powerful reactions as one obtained by any other solvent, thereby showing that the anaphylactogenic protein is water-soluble or at least soluble in water plus the salts contained in the food. Throughout the subsequent work water was used for extraction. As the work progressed, some of the studies of Dr. J. L. Goodale (as yet unpublished) showed that, as a general rule, vegetable foods, boiled, or moderately cooked in any way, furnished just as powerful anaphylactogens as the corresponding raw foods, thus eliminating, in these, all heat coagulable proteins as possible anaphylactogenic factors. From then on, the watery extracts were prepared from cooked foods, because cooking facilitates the extraction. In the case of the fruits, however, this is not so, for the weight of evidence seems to show that heating destroys their anaphylactogenic properties.

It can readily be seen that no one method could be found which was applicable to all

cases. Indeed it was necessary to study each case separately in order to get the best results; but in general the method employed was to soak the material in as large a volume as necessary (often as much as seven or eight liters to four or five pounds) for several days, using thymol as preservative. After decanting and filtering, the volume was reduced by evaporating before the electric fan at room temperature until the substance became syrupy or gummy. When possible (in only two cases) it was spread on paraffin plates and dried over sulphuric acid, and when thoroughly dry was pulverized in a mortar. Ordinarily, however, it was impossible to evaporate to complete dryness, even by the aid of a desiccator and exhaust pump or by digesting in absolute alcohol, for no matter what the process the product was always a thick gum. So after evaporation the substance was dissolved in sufficient water (as determined by preliminary tests) and precipitated by three or four volumes of 95% alcohol. The precipitate was then centrifugized out and washed through several baths of 95% alcohol, absolute alcohol, and then ether, and finally dried over sulphuric acid. In this way a friable powder was obtained, usually white or still retaining slightly the original color of the vegetable from which it was produced.

It was frequently necessary to deviate from this general plan. For example, it was often advantageous to precipitate with a mixture of acetone and ether instead of with 95% alcohol. When this was done the precipitate was put through two or three baths of this acetone ether mixture, then through ether, and the drying completed over sulphuric acid. It was found also that after precipitating with 95% alcohol the acetone ether mixture could be substituted for absolute alcohol in the dehydration process, the only advantage being that it is rather less expensive.

The powder obtained by this method is not always completely soluble in cold water, though in most cases it goes almost entirely into solution, giving a suspensoid or an opalescent solution. However, if the process of dehydration is delayed and the alcohol left on the precipitate for any length of time the precipitate becomes almost completely insoluble. In consequence, the process, from the precipitation with 95% alcohol, on to the drying in the desiccator, must be hurried over as rapidly as possible. For this reason the precipitates were centrifugized in preference to filtration. If, in spite of all precautions, they become only incompletely soluble in water, they can always be dissolved in weak alkali (about 0.1% KOH), and it has been shown that this strength of alkali does not affect the biological reaction.

For the sake of convenience the preparations made by this method may be classified as follows:

I. CEREALS.	IV. ROOTS AND TUBERS.
Barley	Potatoes
Wheat	Boiled potatoes
Wheat bread	Baked potatoes
Rye	Carrots
Corn	Turnips
Rice	Beets
Oats	Parsnips
	Squash
II. NUTS.	V. FRUITS.
Almonds	Apples
Brazil nuts	Oranges
Walnuts	Bananas
III. OTHER SEEDS.	VI. LEAVES AND STEMS.
Peas	Spinach
Boiled peas	Celery
Beans	
Cocoon	

I. *Cereals*: All except rice and oats were treated as described above, and a white powder was obtained almost completely soluble in pure water. It was found that rice and oats could be thoroughly dried on paraffin plates without the use of alcohol or acetone. While the rice preparation could be easily powdered and was completely soluble in cold water, giving an opalescent solution, the oat preparation came out in sheets, not unlike the commercial preparations of gelatin in appearance, and was entirely insoluble in cold water, but would dissolve completely in hot.

The chemical tests showed that in all cases these precipitates were made up largely of protein matter, but in most cases the heat-coagulable proteins were present in small amounts only, the bulk being made up of "proteose" and peptone. Subsequent experiments by the author (unpublished) have shown that, of the two proteoses that can be obtained from wheat flour, one, the natural "proteose" of Osborne ('07, '09) is anaphylactogenic to wheat-asthmatics, while the other, the artificial proteose, obtained by decomposition of the other proteins, is non-anaphylactogenic (cf. also Wells and Osborne, '14, '15).

II. *Nuts*: The large amount of oil present in these nuts was removed by first pressing in a screw-press until no more could be thus removed, then washing through three or four baths of carbon tetrachloride. After the oil was entirely removed and the carbon tetrachloride evaporated off, the resulting meal was treated as indicated above; and in all cases a fine, slightly colored powder was obtained, perfectly soluble. In the case of almonds and Brazil nuts, it was shown by chemical tests to consist largely of protein, but in the case of walnuts the amount of protein was small.

III. *Other Seeds*: Extracts of these are easily precipitated by 95% alcohol, and upon drying a fairly soluble powder is obtained. Chemical tests showed this in all cases to consist largely of protein matter. In the preparation from raw peas an albumin and a proteose could be detected, while in that from boiled peas only a proteose-like body was present.

IV. *Roots and Tubers*: In making these preparations the vegetables were boiled until soft, when they were triturated in the boiling water, plus enough water to make about a liter to .45 kilos, and then allowed to soak for several days. The preparation from raw potatoes was made by grinding up in a meat chopper and allowing to soak in cold water for several days, and the process completed as described above. During the extraction and evaporation, however, the material became jet black, owing to the oxidation of chromogen, and this cannot be removed from the finished product. This difficulty is avoided, however, by using boiled or baked potatoes, because the heating destroys the oxidase, which is the active agent in the oxidation.

Chemical tests show that there is really only a very small amount of protein present in these preparations. The one from raw potatoes showed the presence of a heat-coagulable albumin-like substance and traces of a protein not coagulated by heat, probably the proteose described by Osborne ('96). The cooked potato showed the presence of a proteose or some proteose-like body. The carrot preparation also showed the presence of a proteose-like substance, but in the others no protein could be demonstrated by chemical means.

V. *Fruits*: Great difficulty was experienced here in getting the water-soluble part to precipitate. In the case of bananas, if slightly over-ripe fruit is used, the extract can be made and precipitated in the usual way; but if ripe or under-ripe fruit is used, the ordinary protein precipitants cause a gelatinization of the pectose, which renders it impossible to handle. This same difficulty was experienced with apples and oranges, from which, on this account, no good dry preparation has, as yet, been obtained. At the time of writing these two are still under investigation.

VI. *Leaves and Stems*: These preparations are easily made by the ordinary method. However, in none has any protein been detected by chemical means.

From the foregoing work it was found possible to prepare concentrated watery extracts from all the vegetable foods which are ordinarily responsible for anaphylactic diseases, and put them into an easily available form for making tests.

## THE NORMAL REACTION OF THE SKIN TO STROKING.\*

### A DESCRIPTION OF THE PHENOMENON, AND AN EXPLANATION OF ITS CAUSATION BASED ON REASON AND EXPERIMENT.

BY EDWARD A. TRACY, M.D., BOSTON.

THE deduction that the phenomenon here described is the normal reaction of the skin to a mechanical irritant is based on the fact that it was observed in 1165 out of 1236 individuals examined. Their ages ranged from six days to 83 years. As there were known disease conditions present in the majority of the remaining cases, it strengthens the deduction that the phenomenon under consideration is the normal reaction.

The phenomenon in brief is this: When the skin of a normal quiescent subject is stroked by a wooden instrument (e.g. a wooden tongue depressor or a match) it reacts by a deepening of the skin tint, generally brief in duration, appearing where the stroke was made, or in its immediate vicinity, and then, after a period of about fifteen seconds, by a longer lasting whitish color (in Caucasians), showing itself in the location where the stroke was made. The reaction is seen most clearly when the test is made for it on the rosy cheek of a healthy Caucasian boy or girl. The cheek is stroked across, lightly, once; its tint where stroked is soon seen to deepen, and, after a while, fifteen or more seconds, a pallor takes the place of the redness, the streak of white being very noticeable because of its contrast with the rosy field on which it is displayed. The normal reaction just described consists then of two components, the one, vaso-dilation, and the other, vaso-constriction.

### THE CAUSATION OF THE ABOVE-NOTED PHENOMENON.

Besides the normal reaction described, and consisting of two components—vaso-dilation and vaso-constriction, reactions were obtained in subjects in which one of the components was absent; that is, cases were tested in which no vaso-dilation occurred, the vaso-constriction component being present alone in response to the testing stroke, and other cases were tested in which the vaso-dilation component alone was present.

There must be some cause or causes for such various reactions to the same irritant.

It is assumed that the reactions of vaso-dilation and vaso-constriction of the blood vessels of the skin, originate in nerve stimulation caused by the mechanical irritation of stroking.

To produce the reaction a nerve mechanism is assumed for the reacting blood vessels, similar to that given graphically by Rudzki-Hornowski,<sup>1</sup> and based on the work of Ranvier, Schiff and

Gianuzzi; their diagram illustrating the connection of the local fibrils and ganglia of the sympathetic nerves with the blood vessels at the periphery. It is assumed that this is modified somewhat to allow for a connection with the sensory filaments of the skin, and with the autonomic nerve fibres, that are assumed to be in all of the integument as they are known to be in the integument of the face. This latter connection permits of central stimulation of the mechanism of vaso-dilation.

It is assumed that fibres from both branches of the vegetative nervous system,—the autonomic and the sympathetic,—such as are described by Rudzki-Hornowski<sup>2</sup> as an actuality for the sympathetic system, reach into the intima of the blood vessels.

Now the nerve mechanism, whatever it may be, is manifestly the same in all the subjects tested. One thing, however, reached by this mechanism—the blood—is all important, and it is assumed to be a part of the mechanism concerned in the phenomenon observed. The fact that the sympathetic nerve fibrils reach into the intima, that is, that the nerve mechanism of vaso-constriction is known to come into contact with the blood, is a basis for assuming the blood to be a part of the mechanism. It is thus considered a physical part of the mechanism, just as the vessel's walls are, both being in intimate contact with the nerve fibrils which communicate with near-by ganglia.

As has been said, the nerve mechanism is manifestly the same in all the subjects tested. There is one element in the assumed mechanism, however, that is changeful in every case tested, and that element is the blood continually flowing through the vessels and bathing the ends of the vaso-motor nerves in the intima of the vessels. Besides changing constantly its position, it is changeful in composition, carrying the hormones, activators to various organs, and also the various products of metabolism. It is natural therefore, to look to the blood—the only changeful element in the mechanism under consideration—for a solution of the riddle of the reactions found to occur,—the reaction of vaso-dilation followed by vaso-constriction, as the result of a single stroke irritation, the reaction of vaso-dilation alone in some cases, and the reaction of vaso-constriction alone in other cases.

Mention has been made of the fact that hormones, activity incitors, are carried in the blood stream. These are substances given to the blood streams by the endocrine glands. They are less complex than albumen, and capable of ready osmosis through animal membrane.

We know that adrenalin, one of them, is an activator of sympathetic mechanisms. Polak,<sup>3</sup> from his experiments on glycosuria production, concluded that adrenalin works by acting on the peripheral endings of the sympathetic. We know that this hormone is being constantly supplied to the blood stream.

\* Received on May 22, 1916, for publication.

I have observed, after the therapeutic injection of adrenalin in cases in which, before the administration of it, the vaso-constriction component of the normal reaction to stroking was absent, that after about five minutes, on testing, the vaso-constriction component appeared. This can be explained only by the adrenalin added to the blood stream activating the vaso-constriction mechanism by acting on the peripheral endings of the sympathetic nerve in the intima, its activation being evoked by the irritation of stroking. Here, by direct experiment, Polak's deduction that adrenalin acts on the nerve-endings of the sympathetic is visibly verified.

Thus we have one hormone, adrenalin, with a known incitor action of the mechanism of vaso-constriction. But the phenomenon cannot be explained by this hormone alone. We are obliged to assume the presence of at least two hormones in the blood to produce the three reactions that have been observed: 1, vaso-dilation, brief, followed by a slow-coming vaso-constriction that is comparatively long lasting—the normal reaction; 2, the reaction observed in which vaso-dilation alone occurs; and 3, the reaction observed in which vaso-constriction alone occurs.

We cannot suppose the activation of these reactions to be due to the known hormone adrenalin alone, its presence causing its known action of vaso-constriction on the vaso-motor mechanism and its absence causing vaso-dilation to occur; that would account for but two of the reactions noted above, leaving unexplained the normal reaction, the one most frequently observed,—the reaction of brief vaso-dilation followed by slow and long-lasting vaso-constriction sequential to a single stroke of mechanical irritation.

Therefore two hormones at least are necessary for the causation of the phenomena observed.

Moreover, to explain the phenomena, a nerve mechanism for vaso-dilation is necessary, together with the one generally allowed to exist for vaso-constriction. In other words, the vaso-dilation observed is not due to a mere temporary paralysis of the vaso-constriction mechanism. Let us assume that there is only one nerve mechanism,—the known one of vaso-constriction. It has already been shown that two hormones are necessary to explain the phenomena observed. If both hormones are present in the blood of the vessels and activate the same nerve mechanism, it is difficult to see how the normal reaction could occur unless we assume that the paralyzing hormone acts for a brief time only, being always overcome by the activation of the adrenalin on the mechanism. In the absence of adrenalin, the activation of the paralyzing hormone, evoked by irritant or stimulus, could be long lasting, and account for the sole vaso-dilation reaction to the irritant stroking sometimes observed. But the assumption that there is only one nerve mechanism—the sympathetic—would

not allow for the central origin of stimuli to produce vaso-dilation, because experimental central irritation of the sympathetic fibres never produces vaso-dilation; that is, central stimulation or irritation of the sympathetic fibres always activates the mechanism only in one way, that of vaso-constriction.

Hence the activation of vaso-dilation by central stimulation requires a nerve mechanism for its production independent of the sympathetic mechanism.

If, however, we assume a double nerve mechanism connected with the blood vessels in the skin to be present, a ready explanation of all the phenomena observed is offered.

With a double nerve mechanism we can understand how both could be activated by a single stroke of mechanical irritation. In the presence of the incitor hormones,—hormone X for vaso-dilation, and hormone adrenalin for vaso-constriction,—both nerve mechanisms could be activated at once, and quick and brief vaso-dilation, and slow and long-lasting vaso-constriction occur. If the hormone X—incitor of vaso-dilation—were present alone we should have a strong vaso-dilation reaction as a result of the stroke of irritation. If the hormone adrenalin—incitor of vaso-constriction—alone were present, we should obtain activation of the vaso-constrictors and it would be long lasting.

Such are the phenomena observed, and it appears rational to predicate a double nerve mechanism, one for vaso-dilation and one for vaso-constriction. Otherwise, as has been shown, the normal reaction observed and described cannot be explained.

This theory of a double nerve mechanism of the peripheral blood vessels is also in accord with the facts of central stimulation of certain autonomic nerve fibres causing vaso-dilation of the face, and central stimulation of the cervical sympathetic, causing vaso-constriction of the same region.

As corroborative of this theory of a double nerve mechanism for the blood vessels of the skin, I regard the observations of Meltzer,<sup>4</sup> who noted that stimulation of the vagus [autonomic] produces only a brief after-effect, while stimulation of the accelerator nerve [sympathetic] leaves a long-lasting after-effect. In the phenomenon of the normal reaction described—the vaso-dilation, assumed to be due to stimulation of autonomic fibres, is of brief duration; and the vaso-constriction, due to stimulation of the sympathetic, is long lasting.

As further corroboration of this theory of a double nerve mechanism of the blood vessels of the skin, I here report an experiment of injecting pilocarpine into the skin. Eppinger and Hess,<sup>5</sup> together with other German investigators, have found this drug to be the analogue of the physiological hormone X (or "autonomyn" as they term the hormone) as an incitor or activator of the autonomic nervous system only.

The injection of pilocarpine into the skin was followed by quick vaso-dilation locally and the production of a wheal formation apparently identical with *urticaria factitia*. In other words, pilocarpine, a known activator of autonomic nerve mechanisms, activates a nerve mechanism in the skin that is not the sympathetic mechanism.\* The conclusion is it must be the autonomic nerve mechanism really present in the skin. I have already described an original experiment demonstrating that adrenalin activates the sympathetic nerve mechanism of the blood vessels of the skin.

To recapitulate briefly: The phenomenon observed and here reported of the normal reaction of the skin to mechanical irritation produced by stroking with a wooden instrument, and consisting of vaso-dilation, brief in duration, followed by vaso-constriction, long lasting, the writer holds is caused by a double nerve mechanism, one for vaso-dilation (autonomic) and one for vaso-constriction (sympathetic); together with at least two hormones in the blood stream, the hormone X (Eppinger and Hess' "autonym") activating the vaso-dilation mechanism; the other hormone, adrenalin (or analogue, inciters of sympathetic nerve endings), activating the vaso-constriction nerve mechanism.

#### COROLLARY.

The clinical examination of a patient should include testing for the above described reaction. If both components of the reaction are present, the normal reaction, we know then that the hormones activating the autonomic and sympathetic branches of the vegetative or visceral nervous system are present in the blood. If the vaso-dilation component alone is present we know that the hormone X, or analogues, are in excess in the blood, or that the hormone adrenalin (or pituitrin with analogous action), is in insufficient amount to activate the sympathetic nerve endings in the blood vessels tested. If the vaso-constriction component alone be present, we know that the hormone adrenalin (or analogue) is present in excess in the blood, or the hormone X, or analogues, are present in insufficient quantity to activate the autonomic fibrils in the blood vessels.

\* The vaso-dilation caused by the pilocarpine is not due to paralysis of the vaso-constriction mechanism, because stroking (with a blunt pin) results in a streak of vaso-constriction in the reddened area.

## PROTEIN EXTRACTS IN STATES OF HYPERSENSITIZATION.

BY HORACE M. BAKER, BOSTON, AND  
CLEVELAND FLOYD, M.D., BOSTON.

*Bacteriological Laboratory, Harvard Medical School.*

ANDERSON and ROSENAU in their Harvey lecture define hypersusceptibility as a condition of unusual or exaggerated supersensitiveness of the organism to foreign substances. The term anaphylaxis is similarly used. Numerous observations, extending over a period of years, have been made both on animals and human subjects in regard to the supersensitive state and its relation to various foreign substances.

Clinically, one of the best known examples of anaphylaxis is the hypersusceptibility to pollen showing itself as hay fever. The reactions produced by tuberculin and mallein in suitable individuals are well recognized examples of this phenomenon.

More recently, as the result of much clinical and laboratory work, certain other clinical conditions have lately been grouped as anaphylactic states, notably poisoning following the ingestion of strawberries, fish or eggs, and showing itself by gastro-intestinal manifestations.

In like manner, also, not only the well recognized pollen fever, but rose cold and the condition known as bronchial asthma, come under this head. This latter clinical entity differs somewhat from other hypersensitive states in that there may be several sensitizing factors present playing a definite part in the production of the disease; so that at the present time it would seem possible not only to have various food products playing a part, but also numerous bacterial proteins.

Von Pirquet, from his study of vaccinia and the local reaction produced by the injection of tuberculin, showed that sensitization could be estimated from the local phenomena taking place about the point of inoculation.

Since the development of the so-called von Pirquet test for tuberculosis this method is now extensively used to test states of hypersensitization to various proteins, bacterial and otherwise. While other methods, such as the eye reaction of Calmette in tuberculosis and the use of products of autolysis of the typhoid bacillus distilled into the eye to detect typhoid fever, have been extensively used, for all practical purposes the simpler cutaneous test is the most practical method.

To carry out this test for the detection of hypersusceptibility towards various proteins the preparation of extracts is of considerable importance. In order to get the best results it is essential that the preparations used should readily be held in suspension, should be sterile and should be suspended in a non-irritating and readily absorbable diluent. Where bacterial proteins are under consideration, pure cultures must be secured, free from the media

used, and identification, not only of the type, but of the group of organisms to which they belong, should be complete.

In attempting to devise a method to prepare protein extracts from bacteria or foods, many difficulties have arisen. The first obvious step, however, was to avoid the use of chemicals which would neither form insoluble compounds with the protein present, nor form compounds which might lead to erroneous results. Furthermore, the use of excessive heat may to a considerable degree impair the solubility of some proteins. Desiccation to dryness of a substance requires a considerable period of time, and the use of various extractives offers the opportunity for more or less modification of the material from its original composition.

The following methods have been used:

The frequency with which local reactions take place at the point of inoculation in the use of bacterial vaccines at once suggested the method of Wright as one which could be employed in this work.

Various bacteria grown in pure culture in abundance were suspended in normal salt solution and killed by 60° of heat for 30 minutes. Heavy suspensions were then used to detect sensitization. This method, while simple and relatively quickly carried out, has the objections that the final product is inconstant in its concentration, and the prolonged action of heat may materially modify the protein to be tested.

A second method was that of securing a heavy suspension of a bacterial growth, or of food, in salt solution, centrifuging to produce concentration, and then obtaining the substance, bacterial or otherwise, in a dry form by successive washings with alcohol and ether. A suspension of 5 mg. of the residue in one cc. of 15% alcohol was then prepared. The comparison of these suspensions with others later used showed that these preparations were less soluble and reactions were less readily obtained.

Several modifications of this method were carried out, such as the addition of acetone to the original solution to throw down the suspended protein; the use of 0.5% solution of phenol with  $\frac{1}{20}$  normal sodic hydrate as solvents to the precipitated protein; and the autolysis of various bacterial suspensions under ether vapor, followed by extraction with alcohol and ether. The direct application of the resulting powder to the skin was then made.

All these methods were found to be unsatisfactory in that the extracted protein gave unreliable results or failed to show a reaction where sensitization was known to be present.

The above methods, though unsatisfactory, clearly demonstrated the necessity of obtaining the protein extract in a soluble form and of such strength as to render it possible to show a cutaneous reaction, where food or bacterial sensitization is present.

On account of the great variety of food

products which may give rise to sensitization, some variation in their preparation is necessary. In general the following method is equally applicable to both food and bacterial preparations.

The material to be used is secured in large quantities and suspended in normal salt solution with 0.5% phenol added. A bacterial suspension is autolyzed at a temperature of 48° for 24 to 72 hours, depending upon the organism in suspension. During this process the cellular structure of the organism is more or less completely broken down.

The suspension, immediately following the period of autolysis, is quickly evaporated to dryness by a constant temperature of 40°, thus favoring the reduction of the protein to a soluble form. This latter step is carried out by the following simple device. The suspension to be evaporated (this applies to all protein extracts) is placed in flat bottomed glass dish, over a water bath, with an air current from an electric fan directed over the suspension. The flame under the water bath is protected by a shield to prevent variations of temperature. By this simple device the temperature remains constant and quick evaporation to dryness is obtained.

The evaporated material is collected and is kept free from contamination by immediately transferring the preparation to sterile glass-stoppered bottles and sealed. For testing purposes the powdered extract is ground up with glycerine in the proportion of 10 mg. of the powder to 1 cc. of glycerine. One to two drops of this preparation are used for a test. If the powder is applied to the skin directly a constant standard cannot be established or a sterile preparation cannot be vouched for. The glycerinated preparation insures, with ordinary care, a sterile preparation and a constant strength, thus establishing a standard.

The test is carried out in a similar way to the von Pirquet tuberculin test. The inner side of the forearm is cleaned with alcohol and ether, and two scarifications or similar scratches are made about three inches apart, allowing the oozing of serum only. On one spot or scratch one or two drops of the extract are placed and allowed to soak in. The other spot is kept as a control. Both spots should be examined at intervals of twenty minutes, half an hour and one hour. In many cases the food extracts give quicker reactions than the bacterial extracts. Positive reactions consist of a raised urticarial wheal, surrounded by an area of redness of the skin, somewhat circular in outline and usually from 2 to 7 mm. in diameter.

The possibilities of such a method to determine hypersensitization are far reaching. For example, in such a condition as bronchial asthma, one or more factors may play a part in the sensitization so that a large series of tests may be necessary in order to determine all the factors involved. A detailed history is essential as

well as various skin tests with pollens, food and bacterial extracts. Some such outline as is given below may help to bring out many of the factors concerned in a complicated case.

Symptoms following:

## (a) Inhalation of:

1. Grasses, ragweed, goldenrod, asters, etc.
2. Animal products of: horse, cat, guinea pig, etc.
3. Chemicals, dyes, dust.

## (b) Ingestion of:

1. Grains.
2. Nuts.
3. Fruits.
4. Molluscs.
5. Meats.
6. Milk.
7. Eggs.
8. Fish.

## (c) Infection with:

1. Staphylococcus group.—aureus, albus citreus.
2. Streptococcus group.—Pyogenes, fecalis, anginosus.
3. Pneumococcus group, types 1, 2, 3, 4.
4. Diphtheroid group.
5. Bacillus influenzae.
6. Micrococcus catarrhalis.
7. Friedlaender group.
8. Bacillus ozaenae.

## Clinical Department.

## HAY-FEVER: ITS TREATMENT WITH AUTOGENOUS VACCINES AND POLLEN EXTRACT.

By LEON S. MEDALLA, M.D., BOSTON.

## INTRODUCTION.

This paper is a report of six cases of hay-fever (5 autumnal and 1 June hay-fever) treated with autogenous vaccines. The symptoms in the autumnal cases usually began about the middle of August and would last until late

in November, being relieved after the second or third heavy frost. Five of the six cases have been seen by me for the first time during the attack last year, while the sixth I had under observation since 1911, at which time she applied for treatment for alveolar osteomyelitis or "pyorrhea." The treatment and relief from the hay-fever in this last case was incidental. The extent of time this patient was under observation (5 years) is of value in the discussion of a seasonal disease such as hay-fever.

## ETIOLOGY.

Pollenosis as being the direct exciting cause of this disease is by this time fairly well established. The direct production of typical attacks of hay-fever at any season of the year by having the patient inhale pollen, as reported by Scheppegegrell,<sup>1</sup> is in my opinion more valuable as a means of establishing the etiologic relation of pollenosis to this disease as well as a means of diagnosis than the cutaneous reactions so extensively carried on by Goodale<sup>2</sup> for almost any kind and variety of proteins.

The specificity of intradermal and cutaneous reactions has been greatly undermined by the work of numerous investigators as quoted in two recent articles by Stokes<sup>3</sup> and by the investigations carried out by Stokes himself.\*

The subject of cutaneous reactions is a very complex one, and really embraces the whole problem of the physical mechanism of anaphylaxis, and is entirely beyond the scope of this paper. That much is, I believe, sufficient for our purpose;—that these cutaneous reactions are not due to any specific antigen-antibody reaction; they can be elicited by inert substances such as agar, bismuth subnitrate, etc., and are, therefore, of little diagnostic value.

The wholesale empirical application of the cutaneous tests or "skin scratches" in vaso-motor disturbances will prove, I believe, of very little value, if any, as a diagnostic measure. The attempt to substitute a cutaneous reaction, elicited by bacterial extracts,<sup>4</sup> for bacteriological and cultural findings seems to me entirely unwarranted, more especially in such cases where cultures are obtainable and the infecting organism easily determined.<sup>†</sup>

\* The mechanism of the cutaneous reaction is now held, by practically all investigators on the subject, to be due not so much to the substance introduced parenterally, as to the released elements normally present in the individuals—released by the adsorbing action on the anti-formers by the substance introduced parenterally. Whether the substance be ragweed extract, bacterial extracts, egg albumen, horse keratin, lutin, tuberculin or plain agar matters very little since "cutaneous" reactions can be obtained in apparently healthy individuals with any of the above-named substances for no apparent reason. Why such reactions should occur in some normal individuals and not in others has not been worked out as yet.

† Further investigations will, I believe, disclose that the reason for these skin reactions is due to the general hypersensitivity of the skin of these individuals, similar to the hypersensitivity of their mucous membranes associated with it, as well as a state of lowered coagulability of the blood. Thus the state of the individual, rather than the particular substance used in the test, will be the underlying factor.

The reaction to the bacterial extracts as described by Goodale,<sup>2</sup> lasting from  $\frac{1}{2}$  to 1 hour without going on to papule formation, is, I believe, no reaction at all, since the cutaneous tendency of the skin of such individuals may be sufficient cause for such a transient reaction caused by a "scratch" and the introduction of any substance that would act as an anti-former adsorbent.

The mechanism of the production of hay-fever in the light of these new developments concerning the physical mechanism of anaphylaxis could, therefore, be considered as being due to:

First. The pollen-albumens adsorbing the anti-ferments, thus allowing the natural ferments present in the nasal secretions, mucous membrane, lymph and blood to produce the anaphylatoxin, which, in turn, causes the well-known symptoms of hay-fever.

Second. The bacteria present in the nose are thus enabled to cause infection, aggravating and keeping up the condition which would otherwise have been a slight transient affair. I have already referred to a similar phenomenon in a previous article,<sup>5</sup> in connection with eczema, where the direct exciting etiologic factors responsible for what would otherwise be a *passing dermatitis* produce a true *eczema* because of the superimposed infection with the *staphylococcus aureus*.

Third. The lowered coagulability of the blood of the individual and the consequent dilated superficial capillaries make it easy for any substance to provoke anaphylactic symptoms.

The principal factor in the etiology, namely, pollenosis, is the most important exciting cause in this disease. I feel that only such pollens can produce the disease which, when lodged upon mucous membranes of susceptible individuals, are capable of being attacked and their albumens liberated by the secretions of such mucous membranes. The albumens thus set free adsorb the anti-ferments and allow the normally present ferments (when freed from the inhibitory action of the anti-ferments) to cause toxicity with the production of the well-known symptoms of hay-fever. The mechanism of the natural production of this disease—the adsorption of the anti-ferments—is the reason why one attack makes the individual more susceptible rather than immune to further attacks. For this reason no therapeutic immunization could be expected from the local inhalation of pollens, as Scheppегrell<sup>1</sup> reports having used, or from the subcutaneous administration of pollen extracts. No other more plausible explanation has as yet, in my opinion, been brought forward that would satisfactorily explain the symptom-complex of this disease.

The bacterial relation to this disease cannot be so easily put aside as Scheppегrell<sup>1</sup> would have us do. The constant presence of abundant *staphylococcus albus*, *aureus* or *citreus*, either alone or in combination, in the nose as well as in the conjunctival secretions, in all my patients who returned this year for prophylactic inoculations while in their normal state, is certainly of significance. The vast number of negative cultural findings of the nasal secretions I have personally obtained in patients who applied for various diseases, other than hay-fever, and without any nasal infection, makes me feel that there is a definite rela-

tion between the bacteria isolated from the nose and this disease.

It is true that the bacteria are there without causing the symptom-complex; they cannot, therefore, be referred to as the exciting cause of this disease; their presence, however, is abnormal, and may be the cause of the lowered local resistance preparatory to pollenosis. The bacteria and their products are also probably responsible for making it possible for the conjunctival and nasal secretions to attack the pollens, liberate their albumens and cause the disease.

Thus the presence of the bacteria and their products are, I believe, the deciding factors between an individual's being susceptible to the disease or not; while the superimposed infection which these bacteria cause, following the anaphylactic state (sneezing) due to the pollenosis is, I believe, responsible for the real symptoms of the disease, changing it from a mere transient sneezing spell to a real disease with considerable suffering.

I cannot explain in any other way the startling results obtained in this disease, by myself and by others as found in the literature, with the use of autogenous vaccines. The bacterial element in this disease is, therefore, I believe, of great importance.

The lowered coagulability of the blood is the principal reason why good results have been reported by the use of calcium chlorid in the disease under discussion. This drug, as is well known, raises the coagulability of the blood, making it considerably more difficult for the blood serum to ooze out from the capillaries upon the slightest provocation, as is the case otherwise.

#### BRIEF REVIEW OF THE LITERATURE.

I shall not enter upon a discussion of the results obtained by means of pollen extract or pollen serum administration in the various forms, as found in the literature. From our knowledge, as already referred to, of the mechanism underlying anaphylatoxin production and its consequent symptoms by means of the pollens, it would seem to me that theoretically no success could be hoped for from the pollen extract administration because the pollens produce in nature anaphylaxis and not infection followed by immunity, as bacteria do. Our present-day knowledge of the results of such treatment substantiates my contention. Thus Scheppегrell,<sup>6</sup> who was one of the first men in this country to use and report the pollen "immunizing treatment of hay-fever" in 1909, states in his latest article<sup>1</sup> (March, 1916) that the method was gradually discontinued. The only thing he has to offer, now, for this disease is the preventive treatment by means of the eradication of the various pollen-bearing weeds.

I shall now refer briefly to the results obtained with bacterial vaccines in the treatment

of this disease, as found in the literature. Farrington<sup>7</sup> reports 25 cases treated with autogenous vaccines made up from the bacterial growth obtained from the nose after the symptoms have developed. Out of the 25 patients thus treated, he reports 13 cured, 8 of whom were complicated with asthmatic attacks; 6 were markedly improved, 5 of whom had asthma; 3 slightly improved, all had asthma; and 3 failures, all had asthma. He concluded that "autogenous vaccine offers decidedly more in the treatment of hay-fever than all other methods combined."

Morrey<sup>8</sup> reported 8 cases treated with autogenous nose vaccine, with relief in all.

Strouse and Frank<sup>9</sup> report 13 cases (5 early June fever and 8 autumnal fever) treated with autogenous nose vaccine. Of the 5 with June fever, 2 were cured, 2 were slightly relieved, and 1 greatly relieved; of the 8 cases with autumnal hay-fever, 4 were greatly relieved, 2 relieved, and 2 no effect.

They report 3 cases that have been free from hay-fever until a hot spell in September, at which time these patients had a very severe attack. Most surprising results were obtained, they say, by the administration of autogenous vaccines, the symptoms almost completely disappearing following the first injection. A similar result was obtained in a fourth case. In all these four cases seasonal cures were obtained.

These authors conclude that, of the two methods of treatment, the autogenous vaccines seemed to have given "equal or better results in individual cases," as compared with the results obtained from the use of pollen extract.

#### PERSONAL WORK.

The cases I had under observation were all treated with autogenous vaccines obtained from the nose and throat. The cultures were obtained by passing a sterile swab along the floor of the nose to the posterior wall of the pharynx, being careful to swab off, in withdrawing, the mucous lining of as much of the passage as possible. Cultures are then made in the ordinary way on glucose agar, blood serum, bouillon and blood agar. Several tubes of glucose agar slants are used, sufficient for an auto-vaccine. Cultures are made in a similar way from the throat by swabbing off tonsils and going in as deeply as possible between the pillars of the fauces. Cultures from the eye conjunctiva are made by placing a swab on the cornea toward the inner canthus, covering it up with the lids and having the patient squeeze the lids tight,—the swabs soak in any of the secretion present,—then having the patient release the lids and the swab is removed. The growth, as a rule, was found sufficient at the end of 24 hours for the preparation of the autogenous vaccines,—which is carried out in the ordinary way.

Four of the cases were treated with pollen ex-

tract alongside of the autogenous vaccine. The results obtained, however, in the cases treated with the autogenous vaccine alone, as well as in the four cases treated by the combined method, from the way these same cases reacted to the autogenous vaccine prior to the use of the pollen extract, makes me feel that the pollen extract can be easily dispensed with.

Four of the autumnal cases were seen for the first time during the attack, while the fifth one came in three weeks prior to his usual time of attack. All the five cases with the autumnal fever have been relieved from the hay-fever by the autogenous vaccine for the first time in several years, and can be considered "seasonal cures."

The one early June fever (Case 1) I had under observation since March, 1911, and I believe it is the only case of hay-fever on record on whom autogenous vaccine has been used for that length of time.

The hay-fever in this case has always been accompanied by asthma and has been of over 20 years' standing. The relief in response to the autogenous vaccine was marked, necessitating two to three treatments each year, with no discomfort to the patient. She has had no asthma practically from the beginning of treatment, and with the exception of a slight transient attack of sneezing following a long auto trip, she has been free from hay-fever. She has had no recurrence this year (1916).

No pollen extract has been used in this case, nor did I feel justified in trying anything else, since her autogenous vaccine has given such good results.

This case has been the stimulus of my other cases, and although I have used, in some of the others, the pollen extract alongside of the autogenous vaccine, I feel that the latter is the more important therapeutic agent in this disease.

Probably the best way of presenting the results of this treatment will be by a brief résumé of each case history.

CASE 1. N. W. J. Female, 50 years, March 22, 1911.

*Family History.*—Mother had hay-fever; otherwise negative.

*Past History.*—Negative.

*Present Illness.*—Applied for treatment for advanced alveolar osteomyelitis (pyorrhea); has three loose teeth and lost several from looseness. Has hay-fever and asthma, which begins regularly in June and lasts, as a rule, for six weeks every year; has had it for over 20 years. Cultures from nose showed staphylococcus (weak) aureus. She received ten treatments with autogenous vaccine, ranging in doses from 150 to 200 million at an interval of 5 to 14 days. July, 1911, is feeling well; gums very much improved; "has had no hay-fever this year; is very much delighted over it."

Returned on May 28, 1912, with a slight sneezing attack; "feels hay-fever coming on"; was given an injection of vaccine on the same day and another one on June 8 and June 13; responded very well; hay-fever has not developed. Was again seen

on June 2, 1913, when she came in complaining of "hay-fever coming on following a long auto drive"; received a treatment the same day and another June 9; "has had no asthma the 17th of June, the first time in 20 years; has felt fine and free from hay-fever"; received another inoculation on June 24 and July 9. Was again seen on June 12, 1914, "slight sneezing and hay-fever coming on"; hay-fever has not developed much. Was again seen on June 14, 1915. "Has been free from hay-fever three weeks over this year. Just began to sneeze slightly"; otherwise well; was given 150 million autogenous vaccine. Another treatment on July 6 and July 14. Has been well since; free from hay-fever this year, 1916.

CASE 2. B. M. G., 49 years, male, merchant. July 23, 1915.

*Family History.*—Hay-fever and asthma on mother's side; has an uncle that is suffering from asthma.

*Past History.*—Has had all sorts of children's diseases; otherwise negative.

*Present Illness.*—Complains of hay-fever of 37 years' standing; begins as a rule on the 19th of August and lasts until after the second or third heavy frost, usually is suffering up to the end of November; has used pollantin, with no benefit; has had a variety of treatment by various physicians without any results. Cultures from nose showed staphylococcus aureus and albus. Throat cultures showed strepto-pneumo and M. catarrhalis. Autogenous vaccines were made from the nose and throat cultures. He was tested to daisy, tansy, goldenrod and ragweed; was found positive to goldenrod and negative to the others.

He received 12 injections of his autogenous—nose and throat—vaccines, ranging from 250 to 500 million, at an interval of 3 to 5 days. He also received four inoculations with goldenrod extract, beginning Sept. 11, alongside of the autogenous vaccines.

This patient, aside from a slight attack of sneezing following a long auto trip (on Sept. 1), was free from hay-fever for the first time in 37 years. He was discharged Oct. 9, 1915, feeling very happy over the results obtained with the autogenous vaccines. He is coming back the middle of July for prophylactic inoculations. This case can be considered a "seasonal cure." The four inoculations of goldenrod extract I do not believe had much influence upon the outcome.

CASE 3. K. F. C., 39 years; male; letter-carrier. August 23, 1915.

*Family History.*—Negative to hay-fever.

*Past History.*—Had scarlet fever when a child, accompanied by a serious eye trouble; got over it; has had no serious illness.

*Present Illness.*—Hay-fever and asthma of 22 years' standing; has had the hay-fever for about a week now; has had the asthma for a week previous to that; does not have asthma unless it comes with the hay-fever. Nose markedly swollen, completely clogging up passages; whole pharynx edematous and inflamed. Has had an operation on the nose some years ago, with no relief; was tested to ragweed, goldenrod and daisy; was found markedly

positive to ragweed and negative to the others. Cultures from nose showed a growth of an unidentified bacillus, and a diplococcus from which an autogenous vaccine was made up. He received 200 million of the autogenous vaccine on August 30; had a severe reaction following it; his asthma and hay-fever very much worse that night; was better the next day. Sept. 3 he received half of the previous dose, which was followed six days later by another dose similar to the first; three days after the third inoculation (Sept. 12) his hay-fever and asthma cleared up. He received four more prophylactic treatments at an interval of one and one-half to three weeks, and was discharged cured (Nov. 2) with directions to return next year, a month prior to the time when his hay-fever is due.

This patient was a great sufferer from the hay-fever and asthma,—the most pronounced case I have seen, of 22 years' duration. The way he responded to the autogenous vaccine cannot be emphasized too strongly. He received no ragweed pollen extract. He has been attending to his work all along throughout treatment, and although he has been exposed to considerable ragweed on vacant lots while delivering the mail on his tours, three or four times daily, he has not had any return of his trouble, and can be considered a "seasonal cure."

CASE 4. P. R. F.; age, 51 years; clergyman. Sept. 13, 1915.

*Family History.*—A brother has always had asthma and hay-fever in England; otherwise negative.

*Past History.*—Has been practically well all his life, except for "colds"; has had "continuous local treatment with some spray or other"; had a streptococcus sore throat about two years ago, which affected his leg, suffering considerably.

*Present Illness.*—Hay-fever, definitely pronounced for last three years; previous to that he thought it was just a "cold." Chief complaint is inflammation and itching sensation of the eyes; sneezes considerably; nose gets markedly stuffed up; has to breathe through his mouth; was well while he was up in the mountains; began to be troubled on train on his way home a few days ago. Was tested to ragweed, goldenrod and daisy; was found positive to ragweed and negative to the two others. Cultures from nose showed staphylococcus albus and few streptococci; cultures from throat showed streptococci and pneumococci. Autogenous vaccines were made up. He received five injections of autogenous nose and throat vaccine, ranging in doses from 250 to 750 million, at an interval of two to seven days. Each vaccine inoculation was accompanied by increasing doses of ragweed extract in the opposite arm. There was a very marked improvement in symptoms following the second inoculation, and he was well after the fourth treatment (10 days after the beginning of treatment); was given a prophylactic inoculation on Oct. 1 and another on Oct. 15. Discharged, cured as to hay-fever.

This patient has been very happy over the results obtained in his case with the autogenous vaccine. It remains an open question as to the

benefit derived in this, as well as in the next two cases, from the use of the ragweed extract alongside of the vaccine. I hope to be able to settle definitely this question in a future article. It will be interesting to see how he will fare the coming season.

This patient returned June 8, 1916, for prophylactic inoculations before leaving for England. Has been especially well this winter and is feeling fine now.

CASE 5. C. K. E.; male; 22 years. Sept. 18, 1915.

*Family History.*—Father had hay-fever for the last few years; one brother has hay-fever.

*Past History.*—Negative except for "colds" since he has grown up.

*Present Illness.*—Complains of hay-fever; has had it for the last 12 years; comes on usually in the middle of August, lasts until some heavy frosts appear; has had asthma with it for the last three years. No asthma without the hay-fever, and only at night; was quite bad the last few days; had nose operation; spur removed last summer; had his tonsils removed when he was nine years old. The nose operation has not proved of much benefit to the hay-fever; going near horses bothers him a great deal. Was tested to ragweed, goldenrod and daisies; was found positive to ragweed; negative to the others. Cultures from nose showed staphylococcus albus and citreus.

He received six treatments of autogenous vaccines ranging in doses from 50 to 150 million at an interval of 5 to 14 days. He was given at the same time, in the opposite arm, gradually increasing doses of a 1% ragweed extract solution, beginning with min. 3 up to min. 20.

This patient showed a marked improvement following the first inoculation of his autogenous vaccine, and was free from both the hay-fever and asthma following the second inoculation on Sept. 25. All further treatments were more in the nature of prophylaxis. Was discharged well and told to return a month prior to his usual hay-fever season. He showed a very marked improvement generally and was very happy over the result.

This patient returned June 10, 1916, for prophylactic treatment, feeling very well. Cultures from nose showed a very profuse growth of staphylococcus, citreus and albus. A similar growth was present in cultures from conjunctival secretions from which autogenous vaccines were made. He will be followed up with prophylactic inoculations of his autogenous vaccines without the ragweed. The results will be reported upon in a future paper.

CASE 6. B. W. H.; female; 37 years. Sept. 27, 1915.

*Family History.*—Negative.

*Past History.*—No serious illness except "colds" and sore throats. Has had hay-fever for the last 15 years; begins as a rule on the 16th of August and lasts to the end of November. Went to Bothem and felt no relief; has had considerable

stomach upsets for the last two months; lost 12 pounds; is feeling miserable.

*Physical Examination.*—Negative, except for inflammation of the throat, marked inflammation and edema of the nose. Cultures from nose showed staphylococcus (weak) aureus and diphtheroid bacilli, from which an autogenous vaccine was made; she was tested to goldenrod, daisies and ragweed; was found markedly positive to ragweed and negative to the others.

She received seven treatments with autogenous vaccines, ranging in doses from 100 to 250 million, at an interval of 5 to 7 days. She was also given gradually increasing doses of ragweed extract in the opposite arm, receiving 8 inoculations of a 1% solution, ranging in doses from min. 1/4 to min. 6 of the same solution.

This patient has been free from hay-fever practically since Oct. 16, following the third inoculation of vaccine and the second inoculation of ragweed extract. The injection of 2 min. of the ragweed has given rise to such a marked reaction on Oct. 4 and 11 that it was decided to reduce it to 1/4 min., and gradually go up till she has taken 6 min. as a final dose with practically no reaction locally. Her general condition has been very markedly improved; has gained in weight and has been feeling well generally. It remains to be seen how she will fare the coming season.

#### SUMMARY AND CONCLUSIONS.

The bacteria found in the secretions of the nose and eyes of hay-fever patients previous to their attacks and during their supposed healthy condition are markedly suggestive of the important rôle played by such bacteria in this disease. The presence of the bacteria and their products is, I believe, the determining factor between individuals being susceptible to hay-fever or not, since they may be, in a measure, responsible for the breaking up of the pollen, setting free the albumens and thus causing pollenosis. The bacterial infection, though secondary to pollenosis, is apparently responsible for the difference between pollenosis, producing a mere transient sneezing, or true hay-fever attacks with all their accompanying symptoms.

The good results obtained by the use of autogenous vaccines, as found in the literature and those I had myself, still further suggest the important relation of bacteria to this disease.

The mechanism underlying pollenosis, with its accompanying anaphylactic symptoms, is still an open question. I have called attention to the recent developments in the physical mechanism of anaphylaxis which can be applied to this disease: The anti-ferments being adsorbed by the liberated pollen albumens, the symptoms are then produced by the free ferments, which are normally present in the system, but unable to produce toxic symptoms because of the action of the anti-ferments. These free ferments produce the anaphylatoxins, and they in turn produce the anaphylactic symptoms of

hay-fever, which resemble so closely anaphylaxis due to other sources.

The underlying reason for the success of the treatment with autogenous vaccine in this disease is, I believe, due to the fact that the infection is due, in practically all the cases, to the staphylococcus group of organisms. (Five of the six cases here reported were due to the staphylococcus.—2 *S. P. aureus* alone, 1 *aureus* mixed with *albus*, 1 *albus* with *citreus* and 1 *albus* with strepto. The sixth case showed culturally an unidentified bacillus and a diplococcus resembling the pneumococcus.)

Finally the six cases treated with the autogenous vaccine, here reported, can be said to have resulted in "seasonal cures." The results in these cases have been so decidedly beneficial that one cannot help but conclude that the autogenous vaccine has yielded better results in the treatment of these hay-fever cases than any other therapeutic measure thus far suggested in the treatment of this disease.

## EMBOLIC PNEUMONIA FOLLOWING THE MASTOID OPERATION; REPORT OF THREE CASES.\*

By GEORGE L. RICHARDS, M.D., FALL RIVER, MASS.

Otologist and Laryngologist, Union Hospital.

DURING the last year I have had three cases showing, after the mastoid operation, symptoms of what has apparently been an embolic infarct of the lung, localized and limited, with the early symptoms of a pneumonia, and with an accompanying pleurisy of the same character. I am wondering if cases such as these are not fairly common, and whether the possible occurrence of localized mural thrombi of the lateral sinus should not be considered in the after-handling of our mastoid cases, even when the classical picture of sinus thrombosis is entirely absent.

\* Read at the Forty-ninth Meeting of the American Otological Society, Washington, D. C., May 10, 1916.

CASE 1. R. W. J. Physician. Acute otitis media in right ear June 14, 1915. Incised under ethyl chloride. Relief. Purulent discharge. June 15th pain; June 16th better; June 17th pain. Incised drum again, ethyl chloride anesthesia. No relief from the pain which continued in spite of free discharge, and on June 20th the x-ray showing involvement of the right mastoid, the usual operation for an acute mastoid was performed. The x-ray findings were confirmed, extensive involvement of all the cells being found. The day following he complained of acute indigestion and nausea. June 21st temperature 100° to 102°; June 22d temperature 101° to 101.2°; June 23d temperature 101.6° to 104°. On this date the high temperature was explained by the appearance of definite erysipelas extending backwards, forwards and upwards from the mastoid area. At this time Dr. George L. Tobey, Jr., of Boston, saw him in consultation, the question of sinus thrombosis being under consideration. As there were no chills, the appearance of the erysipelas served in our minds to explain the temperature, which became normal on June 28th. From June 23d to the 27th there was steady disturbance of the stomach and inability to sleep. Aside from this, convalescence was continuous. On July 1st, by his own insistence, and not by advice, he went home from the hospital. On July 4th, after having felt very well for the preceding two or three days, he had a sudden attack of pain in the right lung just below the nipple, accompanied by a temperature of 101° running up to 102.5°, and the spitting up of some bright blood. A diagnosis was made of a localized pneumonia. On July 14th, the twenty-fifth day of the disease, the temperature became normal. On July 20th there was a similar attack in the opposite lung in about the same relative position, and running clinically almost the same course as to temperature and duration, the latter being about four days. From this time onward convalescence was uneventful. At the time it was first considered, did or did not this patient have a mural thrombus of the lateral sinus, a portion of which on two different occasions was later detached, producing an embolic infarct in each lung with a resultant localized pneumonia?

CASE 2. W. A. came under observation on July 13, 1915, for an acute otitis media. An incision in the drum was made under ethyl chloride anesthesia, resulting in immediate relief, but three days later pain re-occurred and a second incision was made. On July 19th an x-ray picture showed involvement of the left mastoid. He was admitted to the hospital on July 21st and on the 22d an operation for an acute mastoid was performed, the patient taking ether rather poorly. The history in the hospital was uneventful from the 22d to the 29th, the temperature not going above 99.5°, and on the latter date he went home at his own request. Three days later, August 2d, he had a sharp pain in his left side, and the diagnosis of pleurisy was given by the attending physician. I did not see him at his home until several days later. Inasmuch, however, as the pain was sharply localized and the attack of rather short duration, in the light of the other two cases here reported I think he had an embolic pneumonia. Recovery was complete, but it was several weeks before the pain in the side had entirely disappeared.

CASE 3. P. H. Male, fifty years old. Sept. 25, 1915, acute otitis media. Drum incised under ethyl chloride. Sept. 26th x-ray picture showed mastoid

involvement, but he refused operation until Sept. 30th, when the entire mastoid area was found filled with pus and broken-down cells. On the day of admission to the hospital the temperature was 99° and on the next day 101° to 102°. In the early morning of October 2d, he complained of a sharp pain in the left lung very decidedly limited and with all the characteristics of embolic pneumonia. There was bloody sputum for a few hours, then frothy. The rest of the lung on each side was free from trouble. The convalescence was uneventful and he was discharged on Oct. 10th.

#### REMARKS.

In all of these cases there was a sudden attack of pain, which on physical examination appeared to be due to shutting off of a portion of lung, that is, to be the result of an infarct following an embolus and with an accompanying pleurisy. Just such symptoms and just such physical signs might be expected to follow the lodgment of a small mural thrombus from the lateral sinus, and its passage down to the right side of the heart, and thence into the lung. In all three cases the trouble appeared on the side of the operation, and that side only, with the exception of the first case, where both sides were affected.—the side of the operation first. There was no uniformity in the time area, the attacks coming in respectively two days, eleven days, twenty-two and twenty-eight days. In each instance, ethyl chloride had been used as the primary anesthetic. Had this anything to do with the case? I think not.

### Book Reviews.

*Oral Surgery.* A Treatise on the Diseases, Injuries and Malformations of the Mouth and Associated Parts. By TRUMAN W. BROPHY, M.D., D.D.S., LL.D., Sc.D., F.A.C.S. With special chapters by MATTHEW H. CRYER, M.D., G. HUDSON MAKUEN, M.D., WILLIAM J. YOUNGER, M.D., F. W. BELKNAP, M.D., CALVIN S. CASE, M.D., D.D.S. With 909 illustrations, including 39 plates in colors. Philadelphia: P. Blakiston's Son and Company.

In his preface the author says, "I wish to emphasize an underlying principle of surgery: so to operate as to leave the parts in as nearly a normal anatomical condition as possible; and further, briefly and concisely to supply students, physicians, dentists, and general and oral surgeons with information relative to the symptoms, diagnosis and treatment of conditions affecting the mouth and associated parts."

The author is unable, in spite of efforts to be brief, to give us a book of less than 1100 pages; it is true that a prodigious number of illustra-

tions are included in these pages; many of these pictures are brilliant, and all of them amplify the text. But it seems, from some standpoints, that students would be better served by a shorter text-book.

The volume is very complete; all phases of oral surgery are covered, even to eugenics and infant feeding! The chapter on Tumors is perhaps less proportionately extensive than some of the others; and the entire subject of anesthesia is included in 32 pages of printed matter and illustrations. But, on the whole, the space is divided fairly in relation to the importance of the various subjects.

So large a book upon a special subject is difficult to review adequately. The volume should become an authority, as its author has been for many years.

*Autoplastic Bone Surgery.* By CHARLES DAVIDSON, M.D., and FRANKLIN D. SMITH, M.D. With 174 illustrations. Philadelphia and New York: Lea and Febiger. 1916.

An admirable and very interesting book of 250 pages. It includes an account of the experimental and clinical work of the authors, and a survey of what seems to them best in the enormous literature which has grown up during the past decade upon this important subject. No final decision is reached in regard to many theoretical considerations, but definite views are offered for practical surgical conditions.

A concise summary at the end of each important chapter is a great convenience to the reader.

The book is cordially recommended to students and surgeons.

*Encyclopedia Medica.* Second edition, under the general editorship of J. W. BALLANTYNE, M.D., C.M., F.R.C.P. Vol. III. Edinburgh and London: W. Green and Son, Ltd. 1916.

The first volume of the new edition of this standard medical encyclopedia was reviewed in the issue of the JOURNAL for Sept. 9, 1915, and the second in the issue for Jan. 27, 1916. This third volume continues the work under the captions from chloroform to dyspnea. The first of these separate articles, and others on cranio-cleido-dysostosis and on legislation for mental deficiency, are new in this edition. The remaining articles are revised or re-written. All the articles on drugs have been revised by Dr. John Orr, the author of the section on digitalis. There are few text-ents in this volume, but several excellent full-page colored plates. The work maintains its important and valuable character.

## THE BOSTON Medical and Surgical Journal

Established in 1812

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, AUGUST 10, 1916

### EDITORS.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States; \$6.50 per year for all foreign countries beyond the Postal Union.

An editor will be in the editorial office daily, except Sunday, from twelve to one-thirty p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager.*  
126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

## THE ACTION OF ALCOHOL.

ABOUT few scientific questions have there been more dispute and less accurate data than about the physiological action of alcohol. The matter is coming into increasing prominence and the attitude toward it of the medical profession is changing. The extension of the prohibition campaign and the inclusion of social and moral issues have made all the more confusion as to the fundamental facts on which judgment must finally rest.

The recent policy of the New York City Department of Health is significant of the growing opinion that alcohol is a public health problem of first magnitude. The Health Department is not in sympathy with effort to regulate the trade in alcoholic drinks by legislation but believes that a proper education of the people in the actual effect of alcohol is the only logical course, and that this course will eventually bring the proper restriction in the use of alcohol as a beverage. This comes back then to the

question of what is the real action of alcohol.

That alcohol in small doses is burned in the body and spares body and food substance has been proved by Atwater and his associates. Exact and controlled experiments on the physiological action of alcohol on metabolism and the nervous system have, however, been few, and reliable data are correspondingly rare. Benedict outlines a program prepared by the Boston Nutrition Laboratory of the Carnegie Institution for the study of alcohol and describes the results to date. (*Science*, June 30, 1916.) Benedict points out that the use of alcohol as a food beverage, especially in Europe where often the food calories of the alcohol are greater than those from the protein of the diet, makes it important and within the province of the nutrition laboratory to undertake investigation of the effect of moderate doses. He recognizes the excessive rarity of objectivity as well as of real uncontaminated scientific evidence. Too often the personal ethical views of the observer have dominated the results.

The program outlined by the Nutrition Laboratory provides for thorough study of the physiological effect of alcohol, in small and in repeated doses, on respiration, digestion and secretion, metabolism and heat regulation. Attention is paid to securing careful basic data on the subjects of experiment and in short every effort has been made to forestall criticism even of the ignorant and captious, and to secure and present definite objective data and also to determine a method of procedure which can be followed in future investigations. Particular attention is given to the psychological effects of alcohol.

The selection of the tests to be employed was determined first by the wish to secure a group of systematically coördinated measurements second to utilize the relatively simple and elementary neuro-muscular phenomena where unknown factors would be reduced to a minimum, and third to select those processes which constituted customary reactions.

Benedict reports that in normal subjects the latent time of the patellar reflex was lengthened on an average by 10%, while the extent of muscle thickening was reduced by 46%. The latent time of the protective lid reflex was increased by 7% and the extent of the lid movement was decreased 19%. The latent time in speech reaction tests was increased 3%. Sensitivity to faradic stimulation was decreased 14%. Little

effect was noted on memory and free association. As for motor coördination, there was a decrease of 9% in the velocity of finger movement and of 11% in the velocity of eye movement. It was observed that the pulse was accelerated, but this Benedict ascribes to inhibition of the inhibitory mechanism of the heart. The greatest changes following the ingestion of alcohol were found to be in those processes least subject to voluntary re-enforcement and control. A considerable practice effect was noted throughout the experiments but even this was more than offset by the action of the alcohol.

The time of the maximum effect of the alcohol was from 90 to 100 minutes after ingestion. Benedict states that contrary to Kraepelin no facilitation effect from alcohol was noted, but that there seemed to be a characteristic depression of the simplest forms of finger and eye movements. He holds this to be presumptive evidence of the effect of alcohol on organic efficiency, but he warns strongly against the uncritical application of these results to industrial processes in general where motor coördination is not the only factor involved.

These studies are not completed and the material already obtained is being further elaborated. Such work when confirmed by independent investigators will give a reliable foundation for the attitude to be assumed toward alcohol as a public health problem.

### HAY FEVER.

THE present issue of the JOURNAL, which is published as a special number devoted to hay fever and anaphylaxis, contains a series of articles devoted to anaphylactic phenomena especially with reference to the disturbances associated with hay fever. Particular attention is directed to the work of Dr. Goodale and his associates. The author's earlier work upon this subject, which has now a special seasonal interest, was published in the issues of the JOURNAL for November 5, 1914, Vol. clxxi, p. 695, and July 8, 1915, Vol. clxxiii, p. 42. In the former issue there appeared also a preliminary article on asthma in children by Dr. F. B. Talbot, whose latest contribution on this subject is included in the present number.

The importance of hay fever as constituting one of the serious inconveniences—though perhaps not so dangerous—in the lives of many persons is probably underestimated except by those

who are personal sufferers. The number of those affected is perhaps also not fully realized. Careful recent estimates show that there are at least 200,000 persons in the United States who suffer from recurrent annual attacks of the disease. It appears now fairly well determined that hay fever is an anaphylactic manifestation characterized chiefly by vasomotor phenomena.

It is perhaps not generally known that ordinances providing for the cutting of weeds likely to disseminate the disease have been adopted in several American cities. Apparently the first of these was an ordinance, originally passed by the council of the city of Savannah, in August, 1900, providing for the removal of weeds and other rank vegetable growth within the city limits. This law was subsequently amended on July 3, 1910. In substance it provides that the owner of private property, or agents acting in his behalf, shall, upon notice from the health officer of the city of Savannah, cut and remove from such property in the city any weeds or other rank vegetable growth. Penalty for failure to comply with this ordinance is fixed at a fine of \$50.00 or imprisonment for 30 days, or both. Similar ordinances were subsequently passed by New York City and by New Orleans.

### DIAGNOSTIC CULTURE OF TUBERCLE BACILLUS.

ANY procedure which will facilitate the early diagnosis of pulmonary tuberculosis, especially in the absence of bacilli in the sputum on ordinary examination, is to be welcomed. The method of Petroff for the cultivation of tubercle bacilli is not a radically new procedure, but it offers a practicable means for isolating tubercle bacilli from the sputum as well as from tissues, and often this method of cultivation will show the bacilli when other examinations fail.

The method is roughly as follows: About 5 cc. of sputum under sterile precautions are incubated for half an hour at 37 degrees with 3% sodium hydroxide. After neutralization with hydrochloric acid and centrifugation, the sediment is planted on a special gentian violet egg yolk medium, and then incubated at between 38 and 39 degrees. The culture tubes are covered with a mixture of yellow wax and petrolatum to prevent drying.

In describing the application of this method

to the clinical diagnosis of tuberculosis, Keilty (*Jour. Exp. Med.*, July, 1916) concludes that the method is not difficult, requiring only a careful degree of attention to detail. He finds that the method is of very practical value in cases where the bacilli have not been found in ordinary examination of the sputum and that it is a diagnostic procedure which should be employed in such cases. A negative result is of course of no significance. He believes that it supersedes the antiformin method, having all of the good qualities of the latter, and some in addition. It is possible by this method, as Keilty demonstrated, to isolate the tubercle bacillus from a throat swab. He also found that by the digestion of tissue with sodium hydroxide and then cultivation according to Petroff, it was possible to demonstrate the tubercle bacilli in tissue and save time over the slower method of animal inoculation.

#### THE MASSACHUSETTS COMMISSION ON MENTAL DISEASES.

GOVERNOR McCALL has nominated the following as members of the new commission on mental diseases under the terms of Chapter 285 of the Acts of the Legislature of this year, in place of the old State Board of Insanity: Director, George M. Kline, M.D., of Hathorne, with a salary of \$7500, for the term of five years; associate directors, without salary: John B. Tivnan of Salem, for four years; Henry M. Pollock, M.D., of Boston, for three years; Charles G. Dewey, M.D., of Dorchester, for two years; Elmer A. Stevens of Somerville, for one year. We think the Governor has made a wise selection in naming Dr. Kline as director. He is a graduate of University of Michigan Medical Department in 1901, and has established a record as an able administrator while superintendent of the Danvers State Hospital for the Insane during the past four years. He had previously served as assistant physician at the Worcester State Hospital, at the Mt. Pleasant, Iowa, State Hospital, and at the State Psychopathic Hospital of Michigan, where he was for six years before coming to Danvers.

Dr. Pollock is a graduate of the College of Homeopathic Medicine and Surgery of the University of Minnesota in 1897, and is superintendent of the Massachusetts Homeopathic Hospital, having been recently superintendent of the Norwich, Connecticut, Hospital for the Insane. Dr. Dewey is a graduate of Dartmouth

Medical School in 1886, was trained under the late Dr. George F. Jelly, and has been examiner in mental disease in the Institutions Department of the City of Boston for many years. Mr. Tivnan was trustee of the Bridgewater State Farm for fourteen years, and latterly chairman of the board, and he has been identified for a long time with the Plummer Farm School and the Associated Charities of Salem. Mr. Stevens is vice-president of the Massachusetts Trust Company of Boston, and was formerly state treasurer, thus representing the business man on the commission.

Under the law, the director is the administrative and executive head of the commission. He is charged with administering the laws having to do with the classes of persons under the supervision of the commission, of preparing rules and regulations, appointing agents and subordinate officers and fixing their compensation, subject to the approval of the governor and council. The thought comes to the student of medical institutional government that the provision of the law requiring that at least two of the associate board, besides the director, "shall be physicians and experts trained in the care and treatment of the insane"—three out of five directors—is an unnecessary requirement, and hampers the governor in his choice of appointees. The desirable qualities in medical men for such positions are, training in administrative work and the ability to labor harmoniously with others for the good of the service. The new commission is a neutral board and does not represent in its membership the proponents of the outgoing paid board of three commissioners nor the preceding unpaid board with a paid secretary. Whether, as constituted, the associate board will be of great assistance to the director in the transaction of the business of the commission remains to be seen. No doubt the Governor had a difficult task to harmonize the warring elements and to find suitable material. The JOURNAL extends its best wishes to the Commission for a harmonious and efficient career.

#### MEDICAL NOTES.

BUFFALO, N. Y., DEPARTMENT OF HEALTH.—The recently issued report of the Department of Health of Buffalo, N. Y., presents a complete and illuminating account of public health administration in that city. A study of the comparative statistical table points out some im-

portant facts. In 1882, when the city's population was 157,000 there were 4212 deaths with 4800 births, or an excess of only 597 births over deaths; this gave the city a death rate of 24.06 and a birth rate of 27.47 per thousand. In 1915, the population was 461,887, with 6853 deaths and 12,683 births, or an excess of 5830 births over deaths; giving a death rate of 14.83 and a birth rate of 27.45 per thousand. Thus, it will be noted that although the population constantly increased, yet the death rate decreased to such an extent that even the actual number of deaths in 1915 was but 852 in excess of those in 1891, while the population had increased by 6223. On the other hand the difference in births amounted to 4374. An analysis of the ages of death shows that out of a total of 6853, the greatest number (916) died between the ages of 50 and 60 years, and the smallest number (31) between the ages of four and five years. It is also notable that 1630 died under two years of age, and 1935 died between the ages of 60 and 100 years.

**SMALLPOX IN GREECE.**—Report from Athens by way of Paris, on July 20, states that smallpox is at present extensively epidemic in Athens and the Piraeus. Compulsory universal vaccination has been ordered. The number of cases is not stated.

**RED CROSS NURSING BUREAU.**—Report from Washington, D. C., on July 31, announces the appointment of Miss Clara D. Noyes, superintendent of the Bellevue Hospital Training School, to be superintendent of the Nursing Bureau of the American Red Cross Society, beginning October 1.

**PROGRESS OF POLIOMYELITIS EPIDEMICS.**—Report from New York on August 4 states that the total number of cases of poliomyelitis in that city during the present epidemic to that date was 4680 with 1025 deaths. In New York State, outside New York City, during the same period there were 545 cases and 51 deaths.

In Massachusetts from July 1 to August 5 there were 131 cases and 17 deaths. Of these, 12 cases were in Boston and 11 each in New Bedford, North Adams, Westfield, and Worcester. In New England, outside of Massachusetts, there have been in Rhode Island 34 cases and six deaths. On Aug. 3 a case was reported at Manchester and one at Keene, N. H.

For the purpose of coordinating research on poliomyelitis, the New York commissioner of health last week invited a number of well known pathologists and bacteriologists throughout the United States to meet in New York City on August 3 and 4, for the purpose of planning a series of investigations likely to effect a successful solution of the problem. Those invited are as follows:

Dr. George J. Adami, McGill University; Dr.

Charles Bass, Tulane University; Dr. Ludwig Hektoen, University of Chicago; Dr. Paul Lewis, Vanderbilt University; Dr. Francis W. Peabody, Peter Bent Brigham Hospital, Boston; Dr. Milton J. Rosenau, Harvard University; Dr. Theobald Smith, Rockefeller Foundation; Dr. Victor Vaughan, University of Michigan and Dr. William H. Welch, Johns Hopkins University.

Associated with these will be the following representatives of the prominent research laboratories in New York City:

Dr. William J. Elser, Dr. Simon Flexner, Dr. Emanuel Libman, Dr. Hideyo Noguchi, Dr. Charles Norris, Dr. William H. Park, Dr. Francis Carter Wood, and Dr. Hans Zinsser.

Those who have already accepted this invitation are Dr. Vaughan, Dr. Rosenau, Dr. Jobling, and Dr. Lewis. The meeting was held in the faculty room of the College of Physicians and Surgeons of Columbia University, and a report of its proceedings will appear in next week's issue of the JOURNAL.

#### EUROPEAN WAR NOTES.

**WAR RELIEF FUNDS.**—On Aug. 5 the totals of the principal New England relief funds for the European War reached the following amounts:

Belgian Fund.....	\$142,155.81
French Wounded Fund.....	107,328.51
Armenian Fund.....	63,181.73
French Orphanage Fund.....	58,741.18
Surgical Dressings Fund.....	41,803.87
Belgian Tobacco Fund.....	33,432.15
Facial Hospital Fund.....	23,916.01
Alles' Tobacco Fund.....	1,504.75

#### MEXICAN NOTES.

**RED CROSS BASE HOSPITALS.**—The full list of twenty-five Red Cross mobile base hospitals under the charge of as skilled surgeons and nurses as our country affords was made public on July 30 by Col. Jefferson R. Kean, Medical Corps, U. S. A., Director General of Military Relief of the American Red Cross. This list not only names the "mother" hospitals and their locations, but in most instances the directors and assistants of the base hospitals, each of which is organized or being organized at an initial cost of \$25,000. Col. Kean also mentions two field columns or ambulance companies. The organizing of these hospitals, which, in war time, would pass under the immediate authority of the War Department and be transported to the base of military operations as they were needed, is considered a piece of war relief, preparedness along scientific and constructive lines, and is based in part on the lessons of the European War. The nucleus for the directing personnel of each base hospital is selected from the staff of a large existing civil hospital and when that personnel is transported, on the outbreak of war, to the base of military operations, they

continue at their respective posts, working in the same team-like fashion they employed in civil capacities. Connecting the evacuation or transfer hospitals of the Army with the base hospitals of the Red Cross are the field columns, two of which are being perfected at an expense of about \$15,555 each.

The Director General of Military Relief made this statement concerning the base hospitals and field columns:

"The medical officers attached to regiments, together with those manning the field hospitals and evacuation hospitals, constitute the medical service of the front. These field and evacuation hospitals would, in the opinion of our readers, scarcely deserve the name of hospitals, since they are marching units and have to be provided with only the simplest and most Spartan equipment. Their furniture is bed-sacks, filled with hay and laid on the ground, or camp cots. There are shelter places where the wounded are received, fed, and protected from the weather on their way to the rear. The service of the front is, therefore, the special obligation of the medical officers of the Army and of the National Guard, and the Red Cross is not permitted to share it.

"The next zone, however, which is called the zone of the line of communications and base, is one in which the Red Cross will provide the greater part of service, as the number of medical officers in the Army Medical Corps and connected with the National Guard is quite inadequate to provide such a service. The hospitals provided by the Red Cross, because they are located at the military base, are called base hospitals. They are of great importance, because they are the first real hospitals provided with beds, mattresses, sheets, and trained nurses which the wounded soldier finds on his journey to the rear.

"The base hospitals will receive regular, volunteer, and national guardsmen alike, and so every soldier whose duty brings him within range of hostile bullets has reason to take a keen, personal interest in the knowledge that in these hospitals is being now enrolled the most distinguished talent in the medical profession in this country.

"Each division of troops requires at least one base hospital. It is equipped to receive 500 patients. Its professional staff consists of 23 physicians and surgeons, two dental surgeons, a chaplain, and 50 trained nurses. To assist the latter are enrolled 25 volunteer nurses' aids. The enlisted personnel numbers 153, while authority is given for the employment of about 15 civilians.

"The Naval base hospitals, of which several are now in course of organization, are of about one-half the size of the Army hospitals. The medical equipment of one of the Army base hospitals is estimated to cost about \$25,000, and of a Naval base hospital about \$15,000.

"This equipment should be purchased in time of peace and kept in store by the government, as, if properly stored, very few of the articles suffer much deterioration, and if the purchase is put off until time of war it is only with great delay and difficulty that it can be secured. To avoid this delay and to render the units promptly fit for service many of the Red Cross Chapters in cities where base hospital units are being organized have raised money to purchase it.

"It was anticipated that arrangements could easily be made for the storage of this equipment service on government reservations, but in this expectation the Red Cross has been disappointed, and most of the Chapters now find that they must make further appeal to individual patriotism and generosity to obtain a storage place for it.

"The great advantage of organizing these units in connection with large civil hospitals is that in this way is secured a personnel who know each other and who are accustomed to work together so that team-work and good organization are possible at the outset."

The following are the Red Cross base hospitals already organized:

*Presbyterian Hospital, New York City*—(Equipment subscribed): Director, Dr. George E. Brewer, also Chief of Surgical Service; Principal Assistant, Dr. Alfred Stillman; Chief of Medical Service, Dr. Warfield T. Longcope; Chief of Laboratory Service, Dr. Karl M. Vogel; Chief Nurse, Miss Anna C. Maxwell.

*Mount Sinai Hospital, New York City*—(Equipment subscribed): Director, Dr. N. E. Brill; Chief of Surgical Service, Dr. Howard Lillenthal; Chief of Medical Service, Dr. R. Weil; Chief of Laboratory Service, Dr. George Baehr; Chief Nurse, Miss Elizabeth A. Greener.

*Belleue Hospital, New York City*—(Equipment subscribed): Director, Dr. George David Stewart, also Chief of Surgical Service; Chief of Medical Service, Dr. Van Horne Norris; Chief of Laboratory Service, Dr. Charles Norris; Chief Nurse, Miss Clara D. Noyes.

*New York Hospital, New York City*—(Equipment subscribed): Director, Dr. Charles L. Gibson, also Chief of Surgical Service; Chief of Medical Service, Dr. Lewis A. Conner, Chief of Laboratory Service, Dr. William J. Elser; Chief Nurse, Miss M. H. Jordan.

*New York Post Graduate Hospital, New York City*—(Equipment subscribed): Director, Dr. Samuel Lloyd; Chief of Surgical Service, Dr. Edward W. Peterson; Chief of Medical Service, Dr. Arthur F. Chace; Chief of Laboratory Service, Dr. Ward J. MacNeal; Chief Nurse, Miss Amy Patmore.

*Brooklyn, N. Y., for Navy*—Equipment subscribed): Director, Dr. W. B. Brinsmade, also Chief of Surgical Service; Chief of Medical Service, Dr. Luther F. Warren; Chief of Laboratory Service, Dr. Robert F. Barber; Chief Nurse, Miss Frances Van Ingen; Asst., Mrs. Lillian H. Read.

*Massachusetts General Hospital, Boston, Mass.*—(Equipment subscribed): Director, Dr. Frederic A. Washburn; Chief of Surgical Service, Dr. George W. W. Brewster; Chief of Medical Service, Dr. Richard C. Cabot; Chief of Laboratory Service, Dr. J. Homer Wright; Chief Nurse, Miss Sara E. Parsons.

*Boston City Hospital, Boston, Mass.*—(Equipment subscribed): Director, Dr. J. J. Dowling; Chief of Surgical Service, Dr. Edward H. Nichols; Chief of Medical Service, Dr. John Jenks Thomas; Chief of Laboratory Service, Dr. Arial W. George; Chief Nurse, Miss Emma M. Nichols.

*The German Hospital, New York City*—Director, Dr. Frederick Kammerer.

#### FIELD COLUMNS.

(Ambulance Companies)

*New York City*—\$10,000 subscribed for equipment: Director, Dr. T. M. Strong.

*Berkeley, Calif.*—Director, Dr. R. T. Legge

**MEXICAN RELIEF FUNDS.**—On Aug. 5 the totals of the principal funds for the relief of Massachusetts troops on the Mexican frontier reached the following amounts:—

Volunteer Aid Fund.....	\$74,467.65
Home Relief Fund.....	2,508.00
Eighth Regiment Fund.....	2,225.00

#### BOSTON AND NEW ENGLAND.

**DIPHTHERIA AT MASSACHUSETTS GENERAL HOSPITAL.**—An outbreak of diphtheria has recently occurred at the Massachusetts General Hospital. On Aug. 6 there were 32 positive cases of the disease, including 29 nurses, two physicians, and one ambulance driver. No patients have been infected and there have been no fatalities. The source of the outbreak is as yet undetermined.

**HAVERHILL BOARD OF HEALTH.**—The thirty-sixth annual report of the Haverhill, Mass., Board of Health states that the death rate of that city for the year 1915 was 13.75 per thousand inhabitants, this being the lowest mortality rate in the history of the city. The total number of deaths was 677. The average age of decedents during the year was 45 years, 10 months and 14 days, the highest in the past thirty-five years.

**MASSACHUSETTS BOARDS OF HEALTH.**—A quarterly meeting of the Massachusetts Association of Boards of Health was held on July 27 at Providence City Hospital with about 75 members in attendance. Addresses were made by Mayor Gayner of Providence, Dr. Charles V. Chapin, Superintendent of Health of Providence, and by Mr. Franz Schneider, Jr., of the Russell Sage Foundation of New York City, on Relative Values in Public Health Work.

**ANTHRAX IN MASSACHUSETTS.**—The Massachusetts Board of Labor and Industries has recently conducted a statistical study of anthrax in this commonwealth. During the year 1915, there were 30 human cases of this disease in Massachusetts, with six deaths. During the year 1916 thus far there have been 22 cases and five deaths.

#### Miscellany.

##### CHANGES IN THE MEDICAL CORPS, U. S. NAVY, FOR THE WEEK ENDING JULY 22, 1916.

July 11.

Surgeon C. D. Langhorne, detached *Oklahoma* to two months leave.

Surgeon M. K. Johnson, detached *Montana* to *Oklahoma*.

July 12.

P. A. Surgeon C. P. Lynch, commissioned from February 19, 1916.

Asst. Surgeon O. C. Foote, detached *Tallahassee* to *Delaware*.

July 13.

Asst. Surgeon Howard Priest, detached *Delaware* to *Tallahassee*.

Asst. Surgeon R. H. Greenough, commissioned May 25, 1916.

July 17.

Asst. Surgeon J. T. Boone, detached *Marine Brigade, Haiti*, to treatment, *Naval Hospital, Norfolk, Va.*  
Asst. Surgeon C. F. Glenn, M.R.C., to *Naval Recruiting Station, Burlington, Vt.*

Asst. Surgeon G. E. Faulkner, M.R.C., to *Recruiting Station, Naval, New Orleans, La.*

Asst. Surgeon L. D. Arbuckle, M.R.C., to *Navy Recruiting Station, Boston, Mass.*

July 18.

P. A. Surgeon J. A. Biello, temporary duty, *Naval Recruiting Station, New York, N. Y.*

July 19.

Asst. Surgeon Henry McDonald, detached *Colorado* to *Pittsburgh*.

#### APPOINTMENTS.

Dr. Victor F. Anderson has been appointed to take charge of the Medical Department and Psychological Laboratory of the Boston Police Corps.

Dr. Lyman A. Jones, formerly district health officer in Berkshire and later in Essex, Mass., has been appointed to succeed Prof. Selskar M. Gunn as director of hygiene of the Massachusetts State Department of Health.

#### RECENT DEATHS.

DR. GEORGE ARTHUR STONE died at his home in Pigeon Cove, Rockport, Mass., July 28, aged 50 years. Dr. Stone was born in Ipswich, Mass., was a graduate of Harvard Medical School in 1880, and joined the Massachusetts Medical Society in the same year. He had practised in Pigeon Cove for 18 years and had been a member of the school board. He was a Mason. He is survived by a widow and one son.

DR. MICHAEL KELLY, a pediatrist of Fall River, Mass., died in that city July 28, aged 62 years. He was born in Ireland, went to Fall River in 1869 and graduated from Holy Cross College in 1879, and from Bellevue Medical College in 1885 when he settled in practice in Fall River. He was chairman of the board of health for seven years, and was a member of the Massachusetts Medical Society from 1901 until February of this year. He leaves a wife and three children.

DR. ADOLPH LAMAR who died of heart disease on July 25, in New York City, was born at Havana, Cuba, in 1869. He was a graduate of the University of Havana and a practitioner and member of the board of health in that city. He is survived by his widow and one daughter.

DR. L. ALBERT NEISSER, Professor of Dermatology in the University of Breslau, died at Berlin on July 30.

DR. SAMUEL SILVA, who died of cerebral hemorrhage on July 30 at Southbridge, Mass., was born at Fayal in the Azores, in 1836. He was a graduate of the Harvard Dental School and had practised his profession in Southbridge for many years.

### Address.

#### TUBERCULAR INFECTION IN INFANCY AND CHILDHOOD.\*

BY VANDEPPEL ADRIANCE, M.D., WILLIAMSTOWN, MASS.

IN the bulletin of the Massachusetts Trustees of Hospitals for Consumption, December, 1913, it was stated: "The importance of childhood infection is coming to be recognized as a most important factor in anti-tuberculosis work. The Board wishes to impress upon physicians and anti-tuberculosis workers throughout the State the absolute necessity of recognizing and treating tuberculous infection in children if we are ever going to make any headway against the disease. There is too much of a tendency to wait until people become sick before we cure them. The bulk of patients at present under treatment in our sanatoria represents the results of infection when they were children."

On August 1, 1914, the same Trustees sent to each physician of the Commonwealth a letter which said:

"It is your opportunity, first, to protect these children from infection, and second, to see that they are cared for when such infection has taken place. If you delay making a diagnosis until actual disease is evident, the case has probably gone beyond the stage when cure is possible. A diagnosis of 'infection', as contrasted with a diagnosis of 'disease' is the key to this problem."

\* Read at a meeting of the Berk-shire District Medical Society.

Under such instructions it behooves us to try to understand the situation as accurately as possible, and it is in order to bring new facts to your attention that I am glad to bring certain statements before you which have been forced upon my attention in the course of recent reading.

Von Behring says, "Tuberculosis in the adult is the result of a song begun in the cradle of the infant," and Biggs<sup>1</sup> states, "The conviction has gradually been strengthened that the first infections from tuberculosis occur during infancy and childhood, and extreme care is required if this is to be avoided in tuberculous families."

It is important for us to do away with the old idea that tuberculosis is inherited, for the experience of pathologists seems to prove that tubercular lesions are extremely rare in the new born. It is no wonder that C. J. Gruber<sup>2</sup> considers a congenital case so unusual as to be worthy of reporting. Tuberculosis is also rare during the first weeks of life, but gradually increases. It is during childhood that the greatest amount of tuberculosis is contracted, however, and people interested in human tuberculosis cannot help being interested in the experiments with cattle at Woodcroft, reported by Harlow Brooks, which show that tubercular cows and bulls can be safely used for breeding, providing the offspring are removed from their infected progenitors and the calves taken away from them directly after birth. In this way pure, tubercular cows which are tubercular may be safely used to perpetuate desirable traits, and great loss to the result of their slaughter is avoided. The offspring, however, should be very strictly cared

antined. This reasoning can be applied to children, for if calves can be saved from infection, it is possible to protect the children of infected parents. Accumulated evidence shows that childhood infection is only the beginning of an adult tuberculosis, and if the children are protected, adult tuberculosis will diminish. This theory rests upon the supposition of a latent tubercle, a view which has lain dormant since it was advocated by Weigert, Harbitz and Patruschky, who wrote upon this subject ten years or more ago, stating that all cases of pulmonary tuberculosis occurring in adult life represent infections in the household in early life.

In order to understand much of the recent progress in our knowledge of tuberculosis the importance of von Pirquet's reaction must be realized. It has changed many of the old ideas and been the basis of many investigations which now flood medical literature; and in order that the physicians of the Commonwealth might better understand the practical application of this reaction, the Trustees informed us a year ago that they wished the profession to know of its practical workings, and offered opportunity at convenient places throughout Massachusetts where the profession might be instructed. The use of the test has modified our views of tuberculosis in childhood. It determines the infection of the patient. Although the infection is suspected, it is definitely proved by the test. It is the appeal of the State Board of Health that the children be protected even against infection, but when infected and proven so by the test, that they be protected against the actual development of the disease. The von Pirquet or tuberculin test is more delicate than a macroscopic examination of the body after death, for it proves an infection even when there are no gross lesions. It tells us when people are infected, although they may appear perfectly healthy and may be passed as healthy by the most searching physical examination. On the other hand, the presence of the test occurs in all stages of the disease. It may be present with a mild infection, with a small area of localized tuberculosis, with an acute general military tuberculosis, or it may be present in the final stages of chronic tuberculosis. The only thing that a positive von Pirquet reaction proves is that there is an infection with tubercle bacilli. On the other hand, when the test is positive, it is not necessary to be pessimistic, for it does not necessarily mean disease.

There is one thing which studies with the von Pirquet reaction have drawn to our attention, namely, that the great mass of tubercular people are infected in the family. Family infection plays a great part in the spread of the disease. A large proportion of infections in individuals are present as the result of infection from one individual to another, and this usually occurs from the old to the young. Infection beginning in adult life is not nearly so

much to be dreaded as infection in the infant, and when we accept this we shall come much nearer to the solution of the anti-tuberculosis problem. When there is an adult with tuberculosis the children of the family should be carefully examined. McCorison<sup>4</sup> emphasized the rôle of family clusters in an address at a recent meeting of the Massachusetts Anti-tuberculosis League. Among the patients which were admitted to the North Reading Sanitarium he found 134 distinct families in which at least three cases of pulmonary tuberculosis occurred. In studying the records of one-tenth of the admissions to the Sanitarium it was proven that a group of at least three consumptives was found clustered about the one who was sent away for treatment. As the result of a study of the spread of tuberculosis in families, by Herbert Lampson<sup>5</sup> of the University of Minnesota, the author concludes, first, that the spread of tuberculosis in families where open cases of tuberculosis exist is greater than it is generally understood to be. Sixty-seven per cent. of the individuals of the families investigated, excluding the center cases, showed evidence of tuberculous infection. In no case where there has been definite proven exposure of a family to an open case of tuberculosis has he failed to find a spread of the infection. In at least ten cases investigated the infection had spread to the limit of available material. Every member of these ten families showed evidence of tubercular infection. On the other hand, he concludes, "When no tuberculosis is found in a family the number of individuals showing evidence of infection is very small." Lampson's report is based largely upon the use of the von Pirquet test, and by its use other interesting results have been obtained, as those of Morris Fishberg,<sup>6</sup> who reports a study of all the children of the tuberculous applying for relief at the United Hebrew Charities of New York during a three months' interval. He reports, of 692 children, 67¼% gave a positive von Pirquet; the proportion of positive reactions during the first year was 15%; two years, 55%, steadily increasing to 74¼% during the period from the 11th to the 14th year.

Vedder and Johnson<sup>7</sup> summarize as follows: "A study of tuberculin tests in 1321 hospital children in St. Louis shows that the percentage of positive reactions reaches a maximum of 44% at the age period of 10 to 14 years."

The experience of Pollock<sup>8</sup> shows that 96% of the children in Vienna were infected before the 15th year, while Hamburger<sup>9</sup> states that 95% of the children in Vienna are infected.

Cahnnetto<sup>10</sup> found during the first year while only 9% were infected, that the percentage kept increasing until it was over 87% at 15 years. Reports from other large European cities show similar results.

Manning<sup>11</sup> of Seattle wrote as follows: "I made a careful clinical study of 228 children

coming to the tuberculosis division of the Seattle Health Department in relation to tubercular surroundings. Of 166 children with definitely known exposure to tuberculosis, 50.6% reacted positively to the von Pirquet test; 49.3% reacted negatively to the same test. Of the 62 children examined with a history of no known exposure, 22.8% reacted positively and 77.4% reacted negatively. Between 10 and 15 years there was the largest number of reactors, 58.1%."

Hillenberg<sup>12</sup> studied a prosperous agricultural community in Germany where no open cases of tuberculosis had been observed for years, yet he found one-fourth of the children between 6 and 14 years showed infection.

You will notice that Manning's results, as well as Vedder and Johnson's, are lower than those of foreign observers. But it is apparent, after studying American and foreign figures, that the proportion of infections increases from year to year till it must be admitted, even in our own country, by the time children reach 15 years of age half of their number have been infected, and most of these from some individual in their own family and not from outside sources. We must frankly admit our ignorance of the number of children infected in small towns, but admit by analogy the fact that there is a gradual increase of the number affected up to 15 years of age. On the other hand, as the number of the infected increases with age, the mortality diminishes. That is to say, the older the child, the better his chances when once infected. Thus Hamburger<sup>9</sup> would have us believe that while 80% of children infected before one year of age die, only 10 to 20% infected after two years die. LaPage,<sup>13</sup> from post-mortem evidence, states that the mortality rises during the first year, reaches its maximum in the second year, and then falls rapidly.

Rogers<sup>14</sup> says, "Before the age of two a positive skin reaction seems to be an indication that the child's life is likely to be short."

Wallstein and Bartlett,<sup>15</sup> after careful study of 1320 autopsies at the Babies' Hospital of New York, state that of the 178 tubercular lesions found, 75% were in subjects under two years of age and only 25% in the older children."

Morse<sup>16</sup> says a very small proportion of the children responding to the von Pirquet reaction, however, have tubercular disease. Those who are well and show no symptoms of tubercular disease are little, if any, worse off than those who have not been infected. In fact, it is probable that in many, if not most instances, they are better off in that they have established a certain immunity to tuberculosis.

Baldwin's<sup>17</sup> ideas have a broader viewpoint than the outlook for one generation. He believes that in the ultimate survival of those who acquire a relative immunity there will be a tendency to diminish the severity of the disease.

By inherited immunity the disease will be combated and reduced in virulence, so that after many generations its severity will be reduced. He believes that the opportunity for infection will react to the benefit of the human race by establishing a gradual immunity.

Fishberg<sup>6</sup> claims that by this method the Jewish race, which pays a very small toll to tuberculosis, has acquired a larger degree of immunity.

Authorities of today believe that the majority of tuberculosis begins in childhood, and the greatest hope for its extermination lies in the prevention of infection in childhood. This means that children must be guarded against infected members of the home circle and forces attention upon the sociological conditions of the child's life.

Where it can be carried out, as in tuberculous dispensaries, careful examinations and von Pirquet tests of all children in tuberculous families must be a part of the routine practice, and when children are in the pretuberculous or tuberculous state they should have the benefit of out-of-door life, general hygienic or sanitarium treatment.

Hess<sup>18</sup> would have New York erect preventoria where the children of tubercular parents could be kept free from the poison of the home life. Yearly physical examinations of all public school children are now customary, and one of the great results is the early discovery of the tubercular or pretubercular state. The principal difficulty is that with our present equipment the diagnosis may be made quite early, but we have not the machinery for treatment. The proper management of such cases at home, when sociological conditions are unfavorable, is indeed difficult and the tendency is to erect institutions to meet the conditions. Open-air schools, sanatoria and preventoria at present seem to be on the increase as a partial solution to the problem, and it is interesting to note that in New York there is a so-called Home Hospital, where a family in which a case of tuberculosis exists is moved to live under bettered conditions, in the hope of preventing the infection of the rest of the family, particularly the children.

It would be unwise to lay too much stress upon bovine tuberculosis when we are just beginning to comprehend the disease in human beings, but we cannot discuss the occurrence of tuberculosis in infancy and childhood without acknowledging a relationship between the two. While the great proportion of infection results from exposure to human cases, we must acknowledge that a certain number of cases originate from tuberculous cattle. It is hoped, however, that any attention drawn to this source of infection will not divert attention from the much larger and more important subject of human infection.

It is generally agreed that, whereas there is a certain relationship between the number of

people infected with bovine and human tuberculosis this appears to vary with age.

The greatest number infected with the bovine variety occur in infancy and childhood and do not increase with age, but this is not the case with the human type, which increasingly manifests itself in adult life.

If we concede that tuberculous infection takes place mostly in childhood, bovine infection assumes a new importance, and the warning of the Massachusetts Board of Health that milk from tuberculous cows is extremely dangerous for young children deserves greater attention.

The Massachusetts Board of Health says in its circular to our profession, "Furthermore, remember that milk from the cows is extremely dangerous for young children, and urge your patients to pasteurize their milk."

Many of us will have a prejudice against pasteurizing milk unless we know it is necessary. But a review of the literature on the presence of tuberculosis in cattle will convince anybody that the danger is a real one.

The United States Bureau of Animal Industry estimates that at least 20 to 30% of the dairy cows in our country are affected with tuberculosis, and I imagine these figures are not far out of the way for our own region.

The results of individual investigators, as well as the British Royal Commission on Tuberculosis and of the German Commission, show that, whereas pulmonary tuberculosis is practically always human in type, there is a considerable percentage of bone, joint, abdominal and lymph gland tuberculosis which is bovine in origin. Park and Krumweide<sup>19</sup> of the New York Board of Health, after collating the results of foreign and American investigation, declare a very high percentage of abdominal tuberculosis and cervical lymphadenitis is due to the bovine bacillus. The percentage of children infected varies according to different observers, but Orth says 10% of all tuberculosis in children is due to bovine infection.

An English observer<sup>20</sup> says "not less than 25% of the tuberculous children under five years of age suffer from an infection of bovine origin," while Rosenau<sup>21</sup> states "one-fifth to one-fourth of all cases of tuberculosis in infants and children are associated with the bovine bacillus."

In Park and Krumweide's series of 1511 cases of human and bovine infection, 12.5% of the fatal cases under five years were bovine. The cases show a high percentage of abdominal tuberculosis and tubercular cervical lymphadenitis due to the bovine bacillus.

The occurrence of the bovine type has been most easily and advantageously studied in infected cervical glands.

Mitchell<sup>22</sup> of Edinburgh, after studying 72 such cases, found 65 cases yielding bovine and only 7 yielding the human type. Eighty-eight per cent. of the children 2 years and under had

been fed on unsterilized cow's milk. Fraser, in the same city, in 100 cases of bone tuberculosis found 62% bovine and 35% human, while 3% yielded both types.

Meleher<sup>23</sup> studied the method of infection in 80 consecutive cases of tubercular cervical lymphadenitis, and found 88% bovine in origin, 12% human in origin. All of these children were under 12 years of age and 84% of those under 2 years of age had been fed on raw cow's milk. He concludes that the infection came from the cow's milk.

A. Stanley Griffith,<sup>24</sup> in a study of cervical gland tuberculosis, showed that the proportion of bovine infections was greatest in children under five years of age, namely, that 90% of such infections occurred under that age.

A. Philip Mitchell,<sup>25</sup> having previously studied the frequency of bovine tuberculosis in glandular tuberculosis in the children of Edinburgh, reported that on the bacteriological examination of 406 samples of milk collected from as many shops there were 82, or 20%, found to contain the tubercle bacilli.

In the present state of our knowledge, we are apt to think of two distinct types of tubercular germs, and yet that they have a certain relationship cannot be doubted. Their actions are similar and their biochemistry is certainly very similar. The two varieties have been found in the same individual. Tuberculin made from the two varieties seems much the same. It is perfectly comprehensible, and in fact a matter of every-day experience, that tuberculin cures certain cases of tuberculosis in human beings which are caused by the human type of germ. It seems equally comprehensible that a bovine tuberculin may cure lesions in man or beast caused by the bovine type. In both these lines experience will teach many practical points, and we shall all be interested as progress is reported. The value of the tuberculin of one variety in its action upon the lesions of another is only suggested by recent literature. At the Tenth Annual Meeting of the National Association for the Study and Prevention of Tuberculosis, Dr. Gililand<sup>26</sup> reported that he had treated cows with a vaccine prepared from human tubercle. (The work was conducted at the Experimental Farm of the Pennsylvania State Live Stock Sanitary Board.) The injections were given at varying intervals and in varying amounts. The vaccinated cows were exposed to infection by close association with badly diseased cows. When vaccination had been properly done the cows were apparently rendered immune but the unvaccinated cows died or developed large lesions. Dr. Gililand particularly calls to our attention the fact that it was the injection of the human type of germ which gave immunity to this group of cows, and believes that the experiments suggest a hopeful outlook, but does not prescribe any practical method of immuniz-

ing cows which can be advocated for ordinary use.

W. L. Moss of Baltimore<sup>27</sup> attempted to immunize calves against tuberculosis. Six calves of approximately the same age, weight and breed were selected from healthy, non-vaccinated cows. Three of these calves were fed from birth with the fresh mixed milk of several vaccinated cows. The three remaining calves were fed during the same period with an equal amount of fresh mixed milk from non-vaccinated cows, proved by the tuberculin test to be free from tuberculosis. At the end of several months all six calves were inoculated with a medium dose of bovine tubercle bacilli. The feeding of all calves was continued as previously until the termination of the experiment. At the conclusion of the experiment a necropsy was performed on one calf from each group and the lesions present compared. The calf which had received milk from immunized cows showed a small lesion at the site of inoculation, about 2 cm. in diameter, containing caseous material and surrounded by a thick fibrous wall. The related axillary lymph glands showed small caseous nodules and there were a few caseous areas in the bronchial lymph glands. The control animal showed at the site of inoculation a caseous abscess, 6 to 8 cm. in diameter, with a thin wall. The related axillary lymph glands were enlarged and caseous, as were also the bronchial lymph glands and those in the region of the gall-bladder. The liver contained from 15 to 20 caseous areas 1 to 5 cm. in diameter. The result of the experiment seems to justify the conclusion that a relative degree of immunity against tuberculosis may be conferred on calves by feeding the milk of vaccinated cows.

Clive Riviere<sup>28</sup> raises an interesting point. Assuming that the bovine type is less virulent than the human, he questions whether it is not doing useful work in protecting against the more virulent human type. He doubts whether we should not take measures to secure a mild bovine infection in the way of establishing a gradual immunity rather than leave our children to risk a first encounter with the infinitely more virulent human organism.

L. Sivori<sup>29</sup> reports that experiments on immunized cows show that antigens and antibodies are found in the milk, though not in such quantities as in the blood, and, furthermore, that animals born of non-immunized mothers show antitoxins and agglutinins in their serum, thus proving absorption of such bodies through the gastro-intestinal canal. He would have us believe that the protective substances in milk immunize against tuberculosis.

Julius Rosenberg<sup>30</sup> believes so thoroughly in the value of immunized milk that he glorifies its use, and feels so confident of its usefulness that he has supplied it free of charge to a number of physicians and hospitals. Some institutions have been supplied with the milk for five

months, and at the time of his writing he had 60 cases to report in which there was positive proof of the value of immunized milk as a remedy in tuberculosis of every type and degree.

If cows immunized against the bovine variety of germ can furnish an antitoxin in the milk which is at all efficacious against the human variety, another link in the chain which unites the two organisms is established. This is only one of the relationships which are being discovered under the searching eye of modern scientific methods.

After having drawn your attention to the prevalence of bovine tuberculosis let us approach it from the standpoint of research by Briscoe and McNeal,<sup>31</sup> based on studies of the herds of the Illinois Agricultural Experiment Station. They conclude:

"The results indicate that well-nourished cows which react to the tuberculin test but otherwise appear normal do not commonly pass tubercle bacilli in their milk. Furthermore, under good conditions of dairy management tubercle bacilli are not likely to be found in the milk of such cows when it leaves the dairy. A certain number of such animals, however, in spite of their healthy appearance, are passing virulent tubercle bacilli from their bodies and are, therefore, a constant menace to everything in their environment. So far as we know there is no practical means of distinguishing between these dangerously tuberculous cattle and those which merely react to the tuberculin test, but are not excreting the bacilli."

There appear to be two ways to avoid the use of milk containing tubercle bacilli. The first is the best in theory but impossible in practice. It would seem a very proper procedure to kill all animals that are proven tubercular by the tuberculin reaction, but from the standpoint of the farmer as well as from an economic viewpoint this is impossible of execution. The popular voice would never tolerate the destruction of capital necessary to such wholesale slaughter. The voice of science would also say that the tuberculin reaction is too uncertain to be a rational guide in such a procedure. Nobody in the present state of our knowledge would venture to diagnosticate all the cows infected or all the cows diseased, and for a long time make shifts must be adopted.

The tuberculin test is of use in certain private herds and selected dairies, and some people demand a certified milk from such dairies. This is only one step which shows that the people are gradually being educated to the desirability of a clean milk, but it does not prove that it can ever be carried out on a wholesale scale. Doing away with all the tubercular cows seems an utter impossibility, and we can never hope to see the day when the milk of tubercular cows is not offered to the public.

A more practical method is offered in pasteurization. The Massachusetts Board of

Health urges that this be commonly adopted, and in many of our dairies it is already in practical use. It is not an expensive method and it does away with many dangerous germs besides the tubercle bacilli. It is a good hygienic measure, which demands its general acceptance by the farmers as well as the endorsement of the medical profession.

## SUMMARY.

1. A positive von Pirquet reaction is a proof of tubercular infection.
2. Tuberculosis in the adult is the result of a song begun in the cradle.
3. Tuberculosis is largely contracted in the home circle.
4. The number of children infected increases with the years of age.
5. A von Pirquet reaction during the first two years of life signifies a bad prognosis, but the mortality decreases as the years advance.
6. Infection with small doses of the germs at infrequent intervals may gradually establish immunity.
7. Infection with the bovine type of tuberculosis occurs mostly in infancy and childhood, while the human type is chiefly manifested in adult life.
8. The bovine type manifests itself chiefly in disease of the bones and lymph glands of the neck and mesentery.
9. There is a possibility that the milk of immunized cows may be useful in the prevention and treatment of tuberculosis in the human.
10. Pasteurization of milk should be generally adopted.

## FRACTURES OF THE LOWER END OF THE HUMERUS.

By W. E. LADD, M.D., F.A.C.S., BOSTON.

FRACTURES of the lower end of the humerus occur with much greater frequency in young patients than in adults. The treatment of these cases at the Children's Hospital has for some years past been fairly uniform. The majority of such cases have been put up in the position of acute flexion termed by Ashurst "hyperflexion." In general, reduction has been accomplished by manipulation only. In a small number, open operation has been resorted to, or a special variation in the position of immobilization, as indicated by the direction of the displacement of the fragments. For restoration of function, massage and passive motion have not been employed, but active motion has been relied upon entirely.

Upon such a general outline of treatment it has been interesting to compare the results secured here with those reported by other surgeons. For this purpose the routine records of the hospital have been studied, and in forty-five cases in which the records were complete and the skiagrams satisfactory, end-results have been secured.

For general consideration these cases have been broadly grouped as fractures of the internal condyle, fractures of the external condyle, and supracondylar fractures. Fractures which pass directly across the two condyles, termed diacondylar by many surgeons, have been classed with the supracondylar fractures. The principles of treatment in the two groups do not vary, nor is this fine anatomical distinction necessary for the interpretation of end-results.

In order to compare the end-results, standard terms of recovery must be adopted. A perfect result, as defined by Ashurst, Neuhof and Wolf, and others, is one in which the full range of motion is preserved and the carrying angle is normal.

An analysis of the work of a few representative surgeons seems more adequate for representing differing surgical points of view than a generalized summary of the entire subject.

The recent work of Neuhof and Wolf, advocating the value of early mobilization and massage, has been carefully gone over with reference to the type of fracture, the method of reduction, and the period of immobilization, as well as the after treatment recommended. The methods they advise are not in accord with either experience or practice here. Within my own observation, cases have occurred in which the size of the callus had been increased and the amount of motion limited by early passive motion and massage.

The practical difficulty to parent and child in

reporting daily for treatment is so great that it must be shown not only that good results can be secured by early mobilization, but that similar results are not secured without it.

The Neuhof and Wolf cases do not appear to me to establish the value of early mobilization and massage, and there is no small amount of intrinsic evidence in the study of their unsuccessful cases that callus is at times increased by the treatment. Their successful cases seemed to be the result of proper reduction and immobilization in the Jones' position, rather than the result of after treatment. To prove their contention, they should present cases put up in acute flexion after proper reduction, not having early massage and passive motion, and giving poor results. This they fail to do, and I have failed to find that such is the case from a fairly careful review of the literature, or from our experience. The high proportion of failure in their cases as a whole, 53%, may be ascribed partly to the fact that many cases were referred late after having been improperly reduced, or immobilized, by other surgeons, and possibly to unusually great deformity. The fact remains, however, that a comparison of the perfect and imperfect results shows that the imperfect cases equal or exceed the perfect cases upon mobilization and massage treatment in all groups except the one in which, in addition to the advantage of the Jones' position of hyperflexion, the cases presented in general slight displacements, generally posterior. One is unable to escape the conviction in the modern treatment of elbow fracture in children, that the imperfect results ought not to exceed the perfect results in any group which receives proper treatment, except that limited group which comes to operation for the correction of already established extreme limitations of movement.

Ashurst, in a comprehensive monograph published in 1910, points out reasons for the frequency of elbow fractures in children. That the age of the patient may be a factor determining other points than occurrence, is not emphasized. That the age is related to an early perfect result is at least suggested in our cases, and it is reasonable to suppose that the degree to which ossification in the bone has progressed, and the growth rate at which calcification is occurring, have a bearing upon the rapidity of repair as well as upon the ease with which fractures are mechanically produced. Treves in his work shows also that time through growth is to be counted upon to improve the immediate result, even where the reduction is imperfect, which finding is substantiated by some of the cases here.

With growth, slight bony prominences from unreduced displacements, or callus, may be removed sufficiently to allow free joint action. The time which elapses before a perfect result is reached is difficult to state, as patients generally fail to report further when a fairly satisfactory result is reached, and the final perfect

result in the majority of cases is seen when the surgeon makes a special examination for the purpose of gathering data.

Ashurst's paper is singular in the report of but one operative case. In the work here we have found that the cases which have proved irreducible by manipulation only, for which we have come to adopt open reduction, are typical in the degree or direction of displacement initially presented in the fracture. Among Ashurst's cases, the two imperfect results in diacondylar fractures, and the one imperfect result in fractures of the external condyle, suggest in the data offered that operative treatment would have been followed here. Two of these, Cases 23 and 33, involved apparently marked displacement of the external condyle; the third, Case 24, a diacondylar fracture with rotated anterior displacement into the joint, shows evident imperfect reduction in the last skiagram after hyperflexion. This belongs in the group for which an internal angular splint, or open reduction, has been found essential here. The results secured by Ashurst by hyperflexion, though not perfect, are excellent under the conditions involved, and the claim is not advanced that better results would have been secured in the clinic here.

In the French literature, the work which has proved most interesting for a special examination of the cases is the monograph of A. Treves, published in 1911, which includes reports of some cases of Mouchet, Kirmisson, and Broca.

Treves' monograph was undertaken primarily from the point of view that late results (*resultats lointains*) of elbow fractures in children were probably more successful than the immediate results, and that limitations of motion to a certain extent gradually disappear, and that the use of passive motion and massage is disastrous to hasten processes which even under conditions of imperfect reduction ameliorate themselves with growth and natural use.

The report reviews 79 supracondylar fractures with 68 perfect results; 42 external condyle fractures with 34 perfect results; 34 internal condyle fractures with 22 perfect results; a total of 155 cases with 88% of perfect results. The cases show a systematic roentgenological study from the first x-ray for displacement to the final skiagram of end-result. The determination of a perfect end-result differs slightly from the one adopted by American writers. A result is classed as perfect where the range of motion is practically complete and the variation in the carrying angle is not sufficient to be a noticeable deformity. A decrease in range of motion, or a positional deflection, therefore, which requires special examination for its detection is treated as negligible, which for all practical purposes is correct.

The treatment in the French cases in many ways coincides with ours. Treves and his colleagues advocate reduction and immobilization in acute flexion in the majority of cases, never

PLATE I.—Supracondylar fracture with rotation, lower fragment.

PLATE II.—Lateral view of same case as Plate I three weeks after open reduction, showing good position and callus.

PLATE III.—Same as Plate II only antero-posterior view.

PLATE IV.—Supracondylar fracture with marked inward and backward displacement. Reduced by open operation.

PLATE V.—End-result of same case as shown in Plate IV one year later.

PLATE VI.—Supracondylar fracture with anterior displacement. The exceptional case for which acute flexion is obviously not applicable.

PLATE VII.—Same case as Plate VI, showing a satisfactory alignment obtained with an internal angular splint.

PLATE VIII.—Fracture of external condyle with rotation of the fragment.

PLATE IX.—End result of case shown in Plate VIII after reduction by open operation.

use massage and passive motion, believing it to be never valuable and frequently harmful. His belief as to operative interference we should usually agree with as regards the type of case, but not as to the time operation should be performed, when necessary.

Personally, Treves does not advise operation except as a last resort from six months to a year after the original lesion, when faulty union has definitely occurred, or in special cases when a nerve is involved. The operated cases given, however, show excellent results from the point of view of improvement, but retain some persistent limitation very generally.

Broca, Monchet, Destot, Vignard and Barlatier advise operative treatment in external condyle fractures where displacement is markedly forward or rotation of the fragment occurs, which agrees with our practice here. Kirmisson and Treves do not agree to this as an immediate resort.

Concerning fractures of the internal condyle, he reports "absolute restoration is more frequent than in any other group," which coincides with our limited experience in this type of fracture here.

From a critical point of view, the following cases from the surgical clinic of the Children's Hospital, and my own practice, have been studied and are presented.

There are 25 cases of supracondylar fractures with 21 perfect results, one of six months' duration, still improving, but with a remaining present limitation of five degrees in flexion, which experience indicates can be added to the perfect results; one operative case involving an ischemic contracture, duration one year, still improving, with a present limitation in extension of 15 degrees. This case at present remains uncertain in its final result, and has been excluded from percentage computations until it can be classed in one group or the other. There are two imperfect results. A total of 84% perfect results have been secured, with a probability that 92% of the cases will be eventually perfect.

An examination of these cases shows that all cases of slight displacement or no displacement gave perfect results; that the four cases operated upon by the writer because the displacement was irreducible by manipulation have given perfect results except for a very slight valgus deflection of the carrying angle in two cases, so slight that I feel quite satisfied to consider the arm perfect. These four cases presented the most serious types of supracondylar displacement.

The two imperfect cases involved special conditions. F. McW., entered the hospital six months after the original fracture for the operative correction of established deformity. A marked adductus varus existed and a range of motion reported as between 1/3 and 1/4 of the normal movement. A wedge-shaped piece of bone was resected to free the external condyle and free the obstruction of the olecranon fossa. I have recently examined this case

eight years after operation. It shows excellent improvement upon the original condition. There is a valgus of five degrees and a limitation in flexion of 10 degrees. (Surgeon, Dr. Burrell).

The second case, E. R., came in with a fracture of the radius and ulna as well as the supracondylar elbow fracture, and with very marked swelling of the arm. Acute flexion could not be used immediately. The correction of the wrist fracture is perfect, and the only loss of motion is 15 degrees in flexion. It is two years since the reduction, and it is possible that the flexion may improve slightly with growth.

A study of the displacement in the group shows it to have been serious, or to have presented special difficulty in 16 out of 24 cases (F. McW. omitted), or in 66.6%, and that in the cases of serious displacement it was possible to reduce three out of every four practically without operation. While acute flexion was used in the majority of cases, an internal angular splint was applied under special conditions in two cases with perfect success. (See X-ray Plates VI and VII.) After reduction, the period of immobilization was determined independently in each case, depending upon the judgment of the surgeon in charge. There is no case in which the period was under three weeks, and none in which passive motion or massage was used.

The cases of external condyle fracture were 16 in all, in 15 of which, or a little more than 93%, perfect results were secured. Of these cases, 6 presented practically no displacement, and 2 very slight displacements. The remaining 8 presented difficulties in reduction, and in 5 of this number the displacement was considered irreducible and open operation was resorted to.

The one unsuccessful case in the series, F. J. C., entered the hospital four months after the original fracture with deformity of the arm and extension limited to 45 degrees. Operation was recommended and was not accepted until ten months later (14 months after fracture). A marked improvement was secured. The arm is limited 20 degrees in extension and has a slightly increased carrying angle and some atrophy of the hand and forearm. This case presented in its initial condition the displacement for which we recommend immediate operation, and was identical with the other four operated cases in all facts except the postponement of operation until long after faulty union had occurred.

The proportion of operated cases is higher in the group of fractures of the external condyle than in any other group. These operated cases present that group upon which the rotation and displacement of the fragment is so serious that no other form of reduction is satisfactory in our experience. The fractured surface of the condylar fragment (See X-ray Plate VIII) is turned upward and outward with general downward displacement. The rotation of the fractured surface of the fragment away from the humeral end makes a return to position, without

entering the joint, practically impossible. This type of fracture was first recognized here by Dr. J. S. Stone, and the technique of the open reduction advocated was developed by him. All of the earlier cases were operated upon by him and to him are due the four perfect results in cases operated upon immediately, and the excellent result from the point of view of improvement in the fifth.

The internal condyle fractures were five in number, and a perfect result was secured in each case. In only one case was the displacement a factor of any difficulty (H. E. C.). Since the fragment came forward into the joint, an internal angular splint was used. The recovery of perfect function was slow. Fourteen months after reduction there was a persistent limitation in extension of 10 degrees. Called in for special examination eight years after injury, the arm was found to be perfect in every respect. The factor of growth emphasized by Treves probably entered into the removal of the limiting prominence and the return of perfect function.

Massing the cases without respect to type, degree of displacement, or special details of after treatment, forty-one perfect results, three imperfect results, and one untraced case of excellent promise one month after treatment have been secured, so that in slightly more than 91% of the cases, a perfect arm has been secured.

The outline of treatment used in these cases has comprised x-ray as well as clinical examination before reduction for the accurate determination of displacement. Reduction by manipulation in all cases amenable to this process. Immobilization in hyperflexion unless swelling of the arm or other fracture complications prevents the most acute position and necessitates some degree of extension. (E. G. and L. P.) In special forward displacements an internal angular splint has proved very effective in securing and maintaining position. Immobilization for a period of three weeks or over. The avoidance of massage and passive motion in after-treatment. The encouragement of natural use of the arm by the child to insure the return of function, with the reliance that the instinctive avoidance of pain will restrict undue movement so long as necessary. Non-interference with a persistent slight limitation in movement, which experience shows that growth will eliminate in time. For displacements which are irreducible, operative reduction is practised immediately after the injury, before swelling has taken place, or a few days later, when the swelling has had time to subside. The operation as practised by us consists in making an incision over the external condyle and carrying it into the site of fracture. In the cases of rotated external condyle fracture, the fragment is rotated back to its normal position and the arm placed in the position of acute flexion which has proved adequate for keeping it in place. In supracondylar fractures a similar incision is

used, and the distal fragment is pried down into place with a blunt dissector or other suitable instrument. The arm is then immobilized in acute flexion. It has never been found necessary to use silver wire or other appliance to hold the fragments in position, and we deem it very unwise to introduce any foreign body at a centre of growth.

From this analysis it is seen that the practice pursued in our clinic and in those of Ashurst, and Treves and his colleagues is very similar, the only difference of importance being that we resort to open operation occasionally in cases that Ashurst would not, and that in those same cases we resort to operation soon after the accident, rather than delaying for six months or a year, as would Treves. With this practice Broca, Mouchet, Destot and others are in accord.

In conclusion, we may state that after a careful study of the work of Neuhof and Wolf, we do not believe that their conclusions are correctly drawn, nor that their results justify the adoption of early passive motion and massage as valuable treatment. That the result of our operative interference in a few selected cases to some extent justifies its employment. That acute flexion is the position of choice for immobilization of the great majority of fractures of the lower end of the humerus, and that when not applicable, common sense will dictate what position and apparatus should be employed to secure proper alignment of the fragments. That from three widely separated clinics, cases treated upon general lines of similarity have yielded approximately 90% of perfect results; and that a fracture of the lower end of the humerus in a child treated properly should result in a perfect arm in nine cases out of ten, and a useful arm in practically every case.

### THE MASSACHUSETTS TUBERCULOSIS DISPENSARIES AND THEIR RELATION TO THE PRACTISING PHYSICIANS.\*

By JOHN S. HITCHCOCK, M.D., NORTHAMPTON, MASS.

*State District Health Officer, Connecticut Valley District.*

ON June 22, 1911, the following Act was approved by the Governor of this State.

"Be it enacted, etc., as follows:

"Every city and town containing a population of ten thousand or more, as determined by the latest United States census, shall establish and maintain within its limits a dispensary for the recovery, treatment and supervision of

needy persons resident within its limits and afflicted with tuberculosis, unless there already exists in such city or town a dispensary which is satisfactory to the state board of health. The said dispensaries shall be subject to the regulations of the boards of health of the cities or towns in which they are respectively situated. A city or town subject to the provisions of this Act which, upon the request of the state board of health, refuses or neglects to comply with the provisions hereof, shall forfeit not more than five hundred dollars for every such refusal or neglect."

In 1914 this Act was amended by providing that the said dispensaries "shall be inspected by and be satisfactory to the state board of health."

No effort was made to enforce this law until 1915, when notices were sent out that cities and towns refusing or neglecting to comply with it after a given date would make their explanations to the attorney-general. A list of minimum requirements which would be satisfactory to the state department of health was sent to each city and town that came under the provisions of the law, and the district health officers went to work explaining, persuading and urging the authorities to action. As a result, on the date set, every city and town concerned had established a more or less effective dispensary. Some got excellent results at once and appreciate the value of the institutions; others haven't seen it clearly as yet. The medical profession is, perhaps naturally, suspicious of a "dispensary," and I wish to explain here what the intent is in this so-called "dispensary plan," and what its relation should be to the practising physician.

The procedures for the protection of the public in the ordinary run of communicable diseases are well known. The diseased person is so isolated and cared for that opportunities to spread the disease to others are reduced to a minimum. Persons exposed to and liable to develop the disease are quarantined and watched until the period of incubation is past. Tuberculosis is exactly like any of these diseases in the fact that it is communicable. It is transmitted from one person to another, probably usually by contact, just as they are, and the same methods of protecting the public would be exactly as effective. But tuberculosis, instead of being an acute trouble, is usually chronic and of long duration; the period of incubation may be interminably long, a person may be infected for many years before he shows signs of being diseased; instead of being an epidemic disease it is endemic, and nearly the entire population are tubercular at some period in their lives. The character and history of this disease makes its control a very different problem from that concerned with diphtheria or scarlet fever. The principles are the same, but their application in the same way would put so large a per cent of the population into quarantine for so long a

\* Read before the Medical Societies of Northampton, Holyoke and Westfield.

time that their support would be a financial problem of magnitude. For these reasons our method of procedure must be modified.

Tuberculosis occurs in many forms. The one with which we are chiefly concerned is the pulmonary type. Other forms,—glandular, bone, skin, abdominal, etc., claim many victims, but are not the commonly transmitted, danger to the public that the pulmonary type is.

From the public health standpoint, persons actively or potentially a public tubercular danger may be divided into three classes. These classes are not sharply differentiated; they overlap and run into each other more or less, but still, for practical purposes the distinction holds pretty well.

*First.* The definite open cases, the "advanced" cases, where the bacilli are being thrown off to the extent of being demonstrable. Those in this class are usually pretty thoroughly diseased, and a large per cent. of them either do not recover, or get well with a permanent handicap.

*Second.* The "incipient" cases, diseased but not throwing off bacilli in demonstrable quantities. These are the favorable cases, with excellent prospects of making good recoveries under proper care.

*Third.* The exposed and probably infected, but not yet diseased persons. This class contains the members of the family and the close friends of the other classes, who have been exposed to infection. They may be able effectively to resist this infection. They may hold it dormant for years and unexpectedly develop tuberculosis after some physical depression. They may develop it quickly and pass into the other classes.

As stated above, there can be no sharp distinction between these classes. If rated on laboratory findings alone, a case classed as "advanced" may not be so extensively diseased as another classed as "incipient," because of the superficial location of the ulcer that is pouring out germs in the one and the deep location of the cavity that is confining them in the other.

For the *first class* we have hospitals. Many cities and one county have their hospital, where the patients are largely bed cases, where they are made as comfortable as possible, where those who can recover are given their opportunity, where friends can readily visit them, and where the "open," dangerous cases are removed from the possibility of infecting their children and friends in their homes. There is at present a movement on foot to establish hospitals in all sections of the State for the accommodation of those cases comparatively near their homes, and the consequent relief of the sanatoria of their present burden of advanced cases.

For the *second class* we have sanatoria. These are located in comparatively inaccessible places, where the excitement of visitors can be kept at a minimum and the favorable, "incipient" cases

can be given their opportunity for recovery. The sanatoria are at present loaded with too great a proportion of cases of the first class. The Rutland Sanatorium, for example, where every effort is made to limit the admissions to the more favorable cases, has about 50% of its beds occupied by "advanced" cases, very effectively shutting the doors of the institution against numbers of the very class of patients for whose benefit the Sanatorium was established.

With these two weapons we have been fighting the disease after it had come into the open, but until now we have taken no public measures to protect and aid those exposed and probably infected, but not yet diseased.

For this *third class* we have established dispensaries. The name is unsatisfactory. A "dispensary" is commonly understood to be a place where people come for *treatment* when they can't afford to pay for it. You know well the uselessness of ordinary "treatment" in tuberculosis, and the State does not purpose to foster quackery. To the physician a "dispensary" often means a place where people get for nothing, things for which they could at least pay him a part of the usual fees, and he looks on it as rather his enemy than his friend. If the tuberculosis dispensary is primarily intended to supervise the third class of patients, viz.—those exposed and probably infected but not yet diseased, it is evident that treatment cannot be a very important part of its work. A certain number of diseased persons will certainly come for treatment and will get it, but that is not the main end and object of the dispensary.

Each dispensary should be a complete reference library of general tuberculosis information and of local epidemiological facts, provided with proper equipment, both material and personal, for the application of this general information to the local epidemiological facts recorded there.

If a case of diphtheria is reported to a local board of health, certain facts should be, and generally are, recorded there at once. Where does the patient live, what are the home conditions, can he be isolated there or must he be removed to a hospital, who have been exposed to the case, where do they live, and what is necessary to do in order to keep them under observation during the period of incubation? Tuberculosis is also a communicable disease, transmitted in about the same way, and is a greater factor in the death returns; but how many of these epidemiological facts in regard to it do you find on record? Usually the date, the name and address of the patient and the name of the doctor reporting it. Often you will find that the death certificate was filed within a few days of this report.

To fight tuberculosis successfully the conditions surrounding each case, and the probable channels of infection from it, must be known and watched, and this is the function of the dis-

persary. It should be the tuberculosis clearing-house of the community. There every one who has a right to the knowledge should be able to turn at once to every detail of epidemiological information necessary to combat the spreading of the infection from any given case. This information must include all pertinent facts regarding the actual case, and also the facts concerning all persons who are and who have been exposed to it so that they may be advised and supervised during the long period of incubation.

The material and personal equipment for the dispensary, as worked out by the state department of health is as follows:

In the circular letter sent to the cities and towns coming under the provisions of the law, a statement of minimum requirements was made. These included a set of uniform printed blanks for records, a simple office equipment, required two rooms with certain conveniences, the attendance of a properly qualified physician for examinations, advice and treatment, and the employment of a dispensary nurse. The estimate of the relative value of these requirements might be stated as, 5% office and equipment, 15% physician and 80% nurse.

The dispensary should be centrally located in order that patients may get to it readily. In most places special rooms have been provided, and often these are in direct connection with the offices of the board of health. Other things being equal, this last arrangement has been a very satisfactory one.

The office equipment called for is sufficient to insure the comfort and convenience of both the officials and the patients, to provide a complete and quickly available system of records and a safe place for storing them.

The part of the physician is an important one. He must be qualified to make pretty delicate differential diagnoses, must be sufficiently interested in the work to stand up under the routine, and must be of such a character and with such a reputation for square dealing among his fellow practitioners that they will not be afraid to send their patients to him for examination. The majority of his duties will lie among those who cannot afford to pay much money for their medical work. Still, no physician can tolerate the alienation of any patient, therefore the man in this position must be one whom the other doctors can and do trust, not only to be square in the matter of diagnosis, but also not to damn them with faint praise or by deprecatory remarks. He must have a large knowledge of human nature. Persons coming to the dispensary for advice and treatment will be, in a large number of cases, of the uneducated, suspicious type. Many of them, the majority perhaps, will be those who are not then sick, but who are protected against being sick in the future, and who will not really believe that they are in any actual danger. At best, it will not be an easy and simple process to get these people to attend with the desirable regu-

larity and frequency. The attitude and the diplomacy of the dispensary physician will often be the crucial factor with them. If they feel that they are getting anything of value from him, either in medicine, sanitary advice or even in cheering and interesting words, they will be more easily induced to keep coming. They may think it is a fool proposition, but the nurse can get them there if there is anything in it for them from their own standpoint. If, however, the doctor is of the wrong sort, it would take a bench warrant to get them there more than once.

The qualifications of the dispensary physician and nurse are as much under the supervision of the state department of health as is the rest of the dispensary equipment. In one city it was suggested that the office of dispensary physician be included among the duties laid by ordinance upon the city physician. This plan was disapproved because city physicians come and go, and a man might well be elected to that office who would be worse than useless in the dispensary.

We allowed an 80% valuation to the nurse, for it is chiefly through the work of the nurse that the information is to be obtained, the information that is the foundation on which the whole dispensary work is built.

"Nurse" is a poor term. She is not really a "nurse," she is a combination of clerk, social worker, directory of sources of available aid, co-worker with every benevolent association, close friend of the patient and his family, employment agency, and the personal agent of every doctor in the community. She must know all about every case in her bailiwick, not only the actual physical condition of the patient, but also the family financial and social conditions that play such an important part in this sickness. This does not mean that she is to drag every case and its contacts to the dispensary, and have them examined and advised there. Such cases as are referred to the dispensary by the board of health, by associations or by physicians, as needing the attention but not able to pay for it, should be examined, watched and advised there. Those who can and do pay their way with their own physicians should, of course, be watched and advised by them. No dispensary nurse should ever go to visit a private case without the previously obtained permission and advice of the physician in charge. If he thinks that for any reason whatever it would be unwise for her to go to any particular case she should not go there. She should get from this physician the facts needed for her records, both concerning the case and the contacts, and get them at reasonably frequent intervals. The physician will soon find that instead of taking work away from his, she is increasing his work in that family. He will make more frequent examinations in order to give her the facts she keeps pestering him about, and what he realizes he ought to know. When a family tells her to

go ahead and visit his patient, he will find that she is constantly urging that patient and family to come to him regularly for examination and advice, that she is his agent and coöperator, instead of an enemy to his pocketbook.

All doctors have some semi-charity patients on whom they cannot afford to spend the time that really ought to be devoted to them. If they send these to the dispensary for regular examinations, with a note or a telephone call to the physician explaining the situation, they will find that the report of the examination will be sent direct to them and that medical and sanitary advice will or will not be given to the patient, exactly as they may direct. No man's patients will be alienated from him; on the contrary, his patients will be advised to go to him at regular intervals, in all probability more frequently than has been their habit.

The nurse, in coming to physicians for details concerning the cases they report to the board of health, is not trying to butt in, she is trying to complete the official information on a public danger, and it is well within the rights and duties of a board of health to ask for such records. They are the base of our plan of campaign, the reports of our intelligence division.

It has been believed for some time that we have about all the laws we need for the control of communicable disease. True, the courts will not allow us to apply them in all cases, notably against incorrigible consumptives; nevertheless, we feel that we cannot get much further with control by laws alone, that our future advances must be by the education of the individual in disease prevention. No one has ever had such an opportunity for placing so much information in the very spot where it is most needed as the dispensary nurse will have. She will be at the focus of the disease, damming its ordinary channels of communication and spread. Her advice to the diseased and to the infected people will be given by the direction of and under the oversight of the dispensary physician or the private physician, according as the case is a dispensary or a private one. Her advice will carry weight and be followed in just the proportion that she has been able to gain the confidence of that family and its physician, and the results of her work in stamping out this disease ought to be little short of marvellous.

She will have information that will be of the greatest value to physicians in their work, information covering the character, methods and red tape of all the institutions in the state, both public and private, that care for tuberculous cases. Tuberculosis is a prolonged, expensive disease, and in many instances, a family who could perfectly well handle the finances of a short, acute disease will need help in this situation. The nurse will know where help is and how to get it.

You see why we estimate the nurse's work at 80% of the dispensary. She has to be a person

of peculiar abilities; no fool need apply. Any one who has to insinuate her friendship into a sensitive, sick family and at the same time keep on terms of open confidence with our touchy profession has no bed of roses. A shut mouth is one of her most valuable assets, and that is not a common human attribute. The doctors can make her work easier when she comes to them or they can make her life pretty miserable and her work very discouraging. It is a hard job at the best and calls for about all there is in a woman—no man could do it.

These descriptions of the dispensary doctor and nurse are, of course, of the ideal. No mere human being could be so comprehensively all things to all tuberculous people as would be the case in a perfect institution of this sort. But as a matter of fact, those now in this work come much nearer the measure of this ideal than you would believe possible. None of them escapes shortcomings along some of the lines, but all of them have their extremely valuable qualifications for the work. They are working hard and are getting results, and, from a clearer understanding by physicians in general of the intent and scope of this branch of the work, there should come a fuller measure of coöperation and a correspondingly greater harvest.

In the past we have been going after tuberculosis from one end and in the middle; we believe that through this dispensary work we shall be going at it from the other end also. The record of the fight is good now; we are reducing the gross amount of the disease, but the wiping out of the remainder will be the hardest part of the work.

The dispensary is established to reach the class of persons not provided for by the sanatorium or by the hospital,—the class of exposed and presumably infected people. Treatment of diseased cases there is a small part of its work. Its greatest service to health officials will lie in its recorded facts covering the situation, physical condition and mode of life of diseased persons who remain in their homes and of those persons who have come in contact with tuberculous cases. Its greatest service to the public will be shown in the improved hygienic conditions in infected households, due very largely to the advice given there by the dispensary nurse. It is believed that the dispensary plan will be of great assistance to the physician and not in any way a hindrance to him. In order to get the best results from its work, the coöperation of the medical fraternity as a whole is needed, and we hope to have this in full measure.

The anti-tuberculosis societies, in combining their social service work with their material and medical attendance, were working along this same line. We hope to be able to carry it still further and get still more complete results by putting this work directly under the authority of those whose official business is to protect the public from disease.

## A YEAR'S WORK OF A LOCAL TUBERCULOSIS HOSPITAL.

BY ALBERT C. GETCHELL, M.D., WORCESTER, MASS.

THE Worcester Tuberculosis Hospital is an addition to a hospital plant the City of Worcester has maintained for several years for the treatment of diphtheria and scarlet fever under the care of the Board of Health. Before this addition was made, it was called The Isolation Hospital. It is now the Belmont Hospital. The name indicates its situation, on a fine hill. Belmont Street is the name of the street on which it is located and "Belmont Street" is the sign on the street car that goes directly to the hospital. The Tuberculosis Building is named the Putnam Ward, in honor of Mr. Henry Putnam, who gave to the city the land on which the building stands.

The building is a substantial brick structure, two stories in height, facing the south. It consists of a central building, in which is the administrative office, an assembly hall, and nurses' living rooms. A wing extends from this building to the west, which is the hospital. The complete plan calls for another wing, extending to the east. Each floor of the medical building has one four-bed room, two two-bed rooms, four one-bed rooms, a sun room with abundant window space, one open ward for sixteen beds, service rooms, and out-of-door porches.

The administrative and medical staff consists of (1) the board of health, the office and laboratory of which is at the City Hall, and is also the headquarters of the tuberculosis nurse; (2) The superintendent of the hospital, who has general charge of the local administration and is the local medical officer; (3) A visiting physician, who makes a visit each week day, seeing every patient on each visit, and makes and records all physical examinations; (4) One male supervising nurse and twelve female nurses.

An out-patient department is maintained at the hospital. This serves as a place for examination and advice for patients discharged from the hospital, patients referred by the city tuberculosis nurse, those referred by other clinics and physicians, and such other poor persons as wish to come for advice and treatment.

Before the hospital was opened, the board of health established the policy that only such persons as had tubercle bacilli in their sputum were eligible for admission. This decision rested on two grounds: first, that the hospital was built and maintained by the city primarily as an instrument of public health, and that bacillary patients only were a danger to the public; and secondly, that it is impossible absolutely to determine that a case of pulmonary disease, especially chronic disease, is tubercular without the evidence of tubercle bacilli. It is not necessary that the sputum be found positive at the time of application. If there is a record of positive sputum at the board of health office, the appli-

cant is eligible. Besides this record a report of positive sputum from the laboratories of the four state sanatoria is adequate. This rule has been held to except in a very few instances of sudden emergency like severe hemorrhage, when the patient could not be taken immediately at the City Hospital, and cases of evident consumption under destitute surroundings. The results thus far have justified this policy and there is no disposition to depart from it.

The hospital was intended primarily for advanced and dying cases and those cases are given precedence of all others. But if there is room, the early curable case is admitted and kept until it can be taken at Rutland. This is a very important work. Suitable daily supervision of all the details of a patient's life, in the interval of ten weeks to three months after application is made before the patient is taken at the sanatorium, spells the success or failure of the cure.

The capacity of the hospital is 55 beds. At present this seems to meet the needs of the city. Very few patients have been kept waiting for admission and all whose needs were urgent have been admitted at once.

It appeared early that many more men applied than women, and the open women's ward upstairs was given up to the men, the relation of men and women being about 43 to 12.

The hospital being built and maintained by the city, it is evident that it be reserved for the bona fide city case and others be admitted only as excess population, or by special arrangement satisfactory to the city, which means that cases having a settlement in other towns in the state shall be suitably and adequately paid for by those towns, and that state cases, able to be moved, and whom it is not convenient for the hospital to care for, be removed by the state to another place. I am sorry to say that neither of these conditions has been satisfactorily fulfilled. Of the 148 patients treated during the year, 51 were not citizens of Worcester.

The discipline of the place has been and is a matter of careful, not to say anxious, thought. The problem is a difficult one. The hospital was built and is maintained by the city at considerable expense and the city, if for no other reason, has a right to look for adequate returns for its outlay of money. No work, public or private, goes by itself. System, order, and control are essential in every activity of life, and particularly in those activities involving the welfare of a group. The purpose of the hospital is twofold: to protect the community from the tubercle disease and to relieve suffering humanity. The difficulties to be encountered in carrying out the physical condition of the patients are many. Many of them are not skilled in the use of the bed and their activities must be carefully supervised. Some have no money to buy food or clothing, and have been in the hospital for months. All these conditions are to be met, and the strain of a continuous effort for the patients' benefit.

own good as well as that of others, and of the institution as a whole. On the other hand the hospital is a place of last resort and, whether the final illness be brief or prolonged, it is the last home that many will have on this earth. So far as any public place can be a home this should be one. The patients should have constant, skillful, sympathetic, kindly care. No effort should be spared to prolong life, or, if that is impossible, by assiduous attention to give the patient, who feels his life slipping away, the comfort of human sympathy and support. The scheme of discipline is based upon the foregoing considerations, and while it is intended to allow the largest freedom compatible with hospital efficiency, the limit of that freedom must be respected on pain, it may be, of summary dismissal. The plan has worked well and we feel convinced that it is the best plan, not only for the hospital, but for the patients, and the safe-guarding of public health.

The number of patients treated during the year was 148—106 men and 42 women. Except one child who was kept at the hospital pending other disposition of her, all were over 14 years of age. Of this 148, 84 had a Worcester settlement, 16 a settlement in other cities and towns of Massachusetts, 43 were state cases, and 3 had settlements undetermined; 3 were classified incipient, 56 moderately advanced, 87 advanced, and 2 non-tubercular; 62 died in the hospital, 9 were transferred to state sanatoria, 9 eloped, 12 men returned to work, 2 were discharged for drunkenness, 15 on request, though they could properly have remained longer, and 16 were discharged against advice. Some of these have died outside during the year, and this number, if it could be known, should be added to the 62 who died in the hospital.

In the out-patient department 140 patients were treated.

The treatment has been hospital treatment modified to meet particular cases. We have not to any extent employed so-called specific treatment such as tuberculin and artificial pneumothorax. The whole hospital has the open window much more than a general hospital. Patients are classified according to their particular needs. Feeble elderly persons with stationary or slowly progressive disease are made as comfortable as possible, relative to the open windows. Those also who have pronounced asthmatic symptoms graduate the open window according to their comfort. The ambulant patients—and they are mostly men—have their beds in the large wards which serve as dormitories. Other patients, as their condition requires, are put in the smaller rooms. Advanced cases near death, particularly if they have been to sanatoria, demand the open window, and the open window is used with others unless they are definitely more comfortable without it. All patients who have a reasonable prospect of either cure or material improvement are closely supervised as to out-of-door life during the day and

the open window at night, and regulated exercise as well as their feeding.

We have carefully studied tuberculosis of the larynx. The larynx of every patient is examined on admission, and once every two months during residence, whether or not there are symptoms. Chest examinations are also regularly made at these times. At any time, however, if there are symptoms, a laryngeal examination is made. Nearly every patient has been examined. Those who have not were those who lived but a few hours after admission, and their condition was such as to forbid examination. Twenty-five had on admission tubercular involvement of some part of the larynx or of the epiglottis, and five developed tuberculosis of the larynx during residence. All these died. Treatment has consisted of complete rest of the larynx by non-use of the voice and systematic general care. As these patients are usually very sick, this is not difficult to carry out.

Local treatment we use as little as possible, and only for symptoms, particularly pain and dysphagia. It is an interesting fact that relatively a few have had pain. Although I know of the laryngeal condition, as a rule, I do not tell the patient of it, and while I ask the attendant often as to pain, I never ask the patient until the information has first come from him. Less than one-third of the cases, I should say, have had pain, and some who have had pain were free from it as they neared the end of life. For the relief of pain we have found inhalations of menthol, anesthesin lozenge, two per cent. cocaine spray, and the injection of eighty per cent. of alcohol into the superior laryngeal nerve useful.

I would not imply by what I have said that more active treatment of laryngeal tuberculosis is ineffective. Indeed our experience with galvano-cautery and the removal of the epiglottis in patients at the Rutland Sanatorium proves the contrary. But in none of these cases have I considered these measures advisable, except one,—a patient who had extensive laryngeal and little lung disease. Hoping that the removal of his epiglottis would relieve his dysphagia and give him a chance for life, I operated on the epiglottis. But it did no good. The disease rapidly extended even over the pharynx and he died.

We have also studied the relation of nasal trouble and tonsils to the pulmonary and laryngeal disease. We have observed no greater incidence of laryngeal tuberculosis in obstructed noses than in unobstructed noses, and we find that enlarged tonsils and history of tonsillar trouble is comparatively infrequent.

The most impressive lesson we have learned is that far advanced pulmonary and laryngeal disease is not incompatible with the ordinary activities of life. We have had several patients, mostly men, who gave a history of only a few days and at most a few weeks' illness, but who were found on admission to have extensive pulmonary and laryngeal disease and lived but a short time.

## A SUGGESTION AS TO THE PREVENTION OF INFANTILE PARALYSIS.

BY W. STEWART WHITTEMORE, M.D., CAMBRIDGE, MASS.

*Assistant Visiting Surgeon to the Cambridge Hospital.*

THERE has been much criticism of the medical profession because of its failure to give out to the public definite advice as to how to prevent infection with infantile paralysis. All the measures which have been suggested thus far have been of the vaguest kind, such as washing the hands before eating and keeping children away from any child who is known to be sick. This criticism is the more justified because those in charge of the fight against the epidemic of infantile paralysis in New York have given the public the impression that we know all about the disease and that there is nothing to warrant alarm on the part of parents. In spite of such reassuring statements, the number of cases has steadily mounted to over five thousand, and the end is not yet in sight.

How much better it would have been to acknowledge frankly that we are in great ignorance as to this disease, which has been studied seriously for less than ten years. We do not yet know what the incubation period is nor how long to isolate a patient after the active symptoms have subsided. To avoid further misunderstanding, the public should be taken into our confidence in this matter and asked to be patient while we experiment with various methods of preventing the infection.

I wish to offer a suggestion as to a possible method of preventing children from becoming infected with infantile paralysis, in the hope that it may be tried out to determine whether it is of value or not. About a year ago, Hektoen and Rappaport<sup>1</sup> published a report on the use of kaolin to remove bacteria from the nose and throat. They found that by insufflating kaolin powder in the nose they were able to remove diphtheria bacilli and also practically all bacteria from the nasal mucous membrane in the course of from three to four days. The swallowing of the powder was followed, likewise, by a rapid disappearance of the diphtheria bacilli from the throat. They found that in scarlet fever the kaolin removed streptococci from the nose very promptly. Their method was to spray the finely powdered kaolin into the nose six or seven times a day at two-hour intervals by the use of a powder-blower, being careful first to have the patient blow the nose to remove any discharge which might block the nasal passages and thus prevent the powder from thoroughly coating the mucous membrane. The insufflation was repeated several times at each treatment.

In order to secure the most thorough application of kaolin to the throat their patients were instructed to swallow very slowly one-third teaspoonful of the powder, four or five times an

hour during the day. In a number of diphtheria carriers, complete and apparently permanent removal of the bacilli was accomplished in this way in from two to four days, and the throat, to a large extent, was freed from all bacteria.

So impressed was I with the results obtained by Hektoen and Rappaport that for the past year I have been using kaolin powder as a routine in the treatment of nose and throat infections. I began by employing it on myself and on members of my family in the treatment of coryza and tonsillitis. I found that it apparently cleared up these infections very promptly, and, moreover, was not irritating, but distinctly soothing in its effects. Similar results were obtained by its use in my private practice.

I made one modification in the method of application of kaolin to the throat. It is rather unpleasant to swallow the dry powder, but I discovered that spraying it upon the mucous membrane of the throat by means of the powder-blower is apparently just as effective as swallowing it.

Although we are still in great ignorance as to the mode of transmission of infantile paralysis, it is pretty well agreed that the most common avenue of infection is through the mucous membrane of the nose. Hence it seems to me logical in combating the disease to use a substance which has been shown to be capable of practically sterilizing the nose and throat and is, moreover, free from any irritating effect. Far from being a chemical poison, it can be swallowed in large amounts without any poisonous effect upon the taker. Its action is peculiar in that it owes "its efficiency in bacterial infections to its action in depriving the bacteria of a suitable culture medium while mechanically burying them alive, separating them from the mucosa and other tissues by a protecting, comparatively impermeable coating."

I should especially urge the use of kaolin as a prophylactic measure in the case of every child or adult who has come in contact with any possible source of infection with infantile paralysis. It has been shown conclusively that healthy persons in whose households the disease occurs are frequently carriers of the infection. Kaolin should also be used by patients suffering from the disease and by those who have recently recovered from it, because swabs taken from the nose have demonstrated the presence of the virus in such persons long after recovery from acute anterior poliomyelitis.

The history of the discovery of the bactericidal action of kaolin or fuller's earth is of interest. Stumpf of Wurzburg noted that human bodies buried in clay did not decompose readily, but seemed embalmed. He began to experiment with the use of *bolus alba*, kaolin, internally and found it of great value in affections of the intestinal tract. In the present European War the Germans have been using it in

cases of cholera, dysentery, and typhoid fever with great success. Stumpf<sup>3</sup> reports that the microscopic findings in the feces of the patients fully warrant its use. Wolff-Eisner<sup>4</sup> states that he believes kaolin a very efficient treatment of cholera. "He regards the kaolin-charcoal treatment as a kind of immunotherapy, basing his belief on Hofmeister's dictum that all the phenomena of immunity are colloid chemical reactions. He believes that the kaolin binds toxins which are beyond the reach of serotherapy."<sup>2</sup> These results suggested to Hektoen and Rappaport the use of kaolin in infections of the nose and throat.

From my own personal experience with kaolin powder in the treatment of infections of the nose and throat during the past year, I suggest its use as a possible method of preventing infection of children and adults with infantile paralysis. It should be insufflated into the nose and throat every two hours during the day. Only by its use in a large number of cases where there has been exposure to possible infection with acute anterior poliomyelitis can it be determined whether it is of value or not.

## PRE-OPERATIVE ROENTGENOLOGICAL EXAMINATION IN CANCER OF THE BREAST.

By JOHN W. LANE, M.D., F.A.C.S., BOSTON.

UP to the present time no completely satisfactory treatment for cancer of internal organs has been found, the nearest approach to the ideal procedure being the excision or cauterization of the growth in its early stages; and statistics from the leading surgical clinics of the world are beginning now to show encouraging results from the employment of early radical surgical measures. It is the purpose of this paper to assist in preventing the valuable radical operation for cancer of the breast from coming into disrepute with the laity.

Every radical operation for cancer of the breast followed by an early recurrence causes not only the patient to lose hope, but also forces a circle of the patient's friends to become distinct and forceful opponents of the surgical treatment of cancer. When a death ensues shortly after a radical removal of the breast for cancer, another and more vigorous body of laymen become antagonists of surgery. The general practitioner of medicine, to whom these

cases are first entrusted, also comes into his meed of distrust for surgery when he sees his patient return from the surgical clinic without a cure, after having been subjected to a frightfully mutilating and depressing surgical operation. Such results of surgery prevent patients with early favorable lesions from seeking the surgical treatment which today offers so much. Early recurrences and early post-operative deaths are due, not to the operation *per se*, but to the performance of this efficient operation upon badly selected and already hopeless cases.

Before approaching the actual methods of procedure, which the title of this paper suggests, it is well to recall a little of the pathology of carcinoma and consider briefly its method of metastasis. The dissemination of cancer occurs in several ways,—through the lymph and blood vessels, and by fascial permeation. Cancer cells ulcerate into the lymphatic stream and blood vessels, especially the veins, and are thus distributed to various parts of the body. The permeation theory is expounded by Handley and is based on the observation of many post-mortem cases, and at present is strongly accepted. This theory propounds in the main that cancer of the breast extends by columns of cells along the deep fascia, attacking first, naturally, organs or structures in the immediate neighborhood of the growth. Thus, in cancer of the breast, the pleura, the liver and the long bones, at sites where the deep fascia is inserted in them, are early affected. It is very rare to see cancer of the bones of the forearm or leg, because the patient is usually dead before such condition could exist, but organs and skeletal structures remote from cancer of the breast are often attacked by its dissemination; and once a cancer of the breast has metastasized to other organs, operation is useless. It is necessary, therefore, to operate before these metastases take place, and no operation should be undertaken until this dissemination has been ruled out, and it seems to me that the best method of determination of the existence of a metastasis is by roentgenological examination.

In the past year it has been my custom to subject every case of cancer or suspected cancer of the breast to a very complete roentgenological examination. It has been possible by this means to demonstrate in many cases metastases in the skeletal structure although clinically there was no evidence of their existence. We have demonstrated metastases in the mediastinum, in the femur, pelvis, spine and humerus; but not as yet, to our complete satisfaction, have we been able to demonstrate a pleural dissemination. Of course these cases were prevented from going to the operating table, and thus were not subjected to needless surgery. In two of the cases death has already ensued, and in two others, at this writing, is imminent.

I now wish to advocate as a routine, pre-

operative procedure, the examination, roentgenologically, of the chest, pelvis, spine, humeri and femora in all cases of suspected cancer of the breast. It may be objected that this method is expensive. That is true; but expense matters little when useless surgery is prevented. It may also be urged that a radical operation relieves suffering and prolongs life even in advanced cases; but actually how much longer is life preserved and how much suffering is saved than would be the case under skillful medical treatment? As far as I am aware, this is an original method,—as I have not seen any advocacy of it in the literature,—and is presented with the hope that it will help to safeguard the radical operation for carcinoma of the breast, which is fast coming into ill-repute with the people.

#### AURICULAR STANDSTILL: AN UNUSUAL EFFECT OF DIGITALIS ON THE HEART, WITH ESPECIAL REFERENCE TO THE ELECTROCARDIOGRAM.

By PAUL D. WHITE, M.D., BOSTON.

[From the Medical Service of the Massachusetts General Hospital, Boston.]

DIGITALIS may affect the human heart and electrocardiogram in a variety of ways. A total bradycardia may occur in which the pacemaker in the sinoauricular node is depressed and slowed. Heart-block may be produced, varying from delayed A-V conduction to complete block, the grade depending on the amount of digitalis given and on the condition of the A-V conduction system. Ventricular escape may occur, due to a decrease of sinoauricular rate below the rate of the atrioventricular nodal pacemaker or to an increase of the lower nodal rate over that of the upper node. Aberrant ventricular complexes in the electrocardiogram may follow digitalis administration. In cases of auricular fibrillation large amounts of digitalis may produce a bigeminy due to the occurrence of ectopic ventricular contractions at every second beat. The shape of the *T* wave of the electrocardiogram is definitely altered by digitalis; if, for example, the *T* is upright in Lead II, it becomes depressed and finally inverted as the result of the administration of digitalis.

There is one further effect which may occur in diseased hearts after digitalis, which has not hitherto been described as such, so far as I am aware. That is the removal by digitalis of all evidence of auricular activity from electrocardiogram and from the jugular pulse tracing. There is no evidence that the auricle is contract-

ing at all. Against the possibility of an isoelectric *P* in Lead II is the absence of *P* in Leads I and III also, and the absence of *a* in the jugular pulse. Auricular fibrillation may be excluded by the entire absence of fibrillation oscillations of the galvanometric string and the perfectly regular ventricular rate. The atrioventricular node is probably giving rise to the ventricular complexes, because their shape is that of the normal complexes of supraventricular origin and they occur regularly. No deflections appear suggesting that the atrioventricular node is also giving rise to auricular activity. In other words, there appears to be *auricular standstill*. This condition has been produced experimentally in the cat<sup>2</sup> by depression of the sinoauricular node by cold and depression of the junction of auricle and atrioventricular node by asphyxia.

Three cases have been found at the Massachusetts General Hospital in which this digitalis effect has been seen. All three showed definite evidence of auricular action in electrocardiogram and jugular pulse tracings after the effects of the digitalis intoxication had worn off; in all three the A-V conduction time showed some delay during the recovery from the digitalis. In none of the three, at the time of the disappearance of auricular activity, was there any evidence of auricular fibrillation, ventricular escape or complete atrioventricular rhythm.

Lewis<sup>3</sup> has reported one case of unusual bradycardia in which there was no trace of auricular activity in electrocardiogram or jugular tracing. No note was made as to digitalis administration in this case.

Electrocardiograms from the three cases seen at the Massachusetts General Hospital, without evidence of auricular activity, are shown in Figs. 1, 3 and 4. A short account of these cases follows:

CASE 1. Man of 80 years, with arteriosclerosis and myocardial weakness. In June, 1914, a polygram showed a long *a-c* interval in the jugular pulse. On March 11, 1915, after about 2.5 grams of digitalis in the course of three weeks, electrocardiograms showed no *P* wave but did show a definite digitalis effect on the *T* wave, consisting of inversion of this deflection (Fig. 1a). Diastole was smooth, without evidence of auricular fibrillation. The ventricles were beating regularly. Fig. 2a shows a polygram taken this same day, also without evidence of auricular action. At other times this patient has shown ventricular escape with simultaneous auricular and ventricular contractions; when auricle and ventricle beat simultaneously, very large waves occur in the jugular pulse, representing *a* and *c* joined *a* together. (Fig. 2c.) Digitalis was stopped, and on March 21, 1915, a polygram showed normal rhythm with a long *a-c* interval, and a pulse rate of 40 (Fig. 2b.) An electrocardiogram of April 9, 1915, shows the normal rhythm with the *P* wave present in every lead, and the *T* wave returned to normal (Fig. 1b).

CASE 2. Man of 69 years, with arteriosclerosis and

FIG. 1.

In Figs. 1, 3 and 4 abscissa = 0.2 second; ordinate = 10-4 volt.

- a. The three electrocardiographic leads of G. H. A. showing digitalis effects—absence of auricular deflections and invert *T*. Rate = 39. March 11, 1915.
- b. The three leads of G. H. A. showing normal rhythm with *P* present in every lead. *P-R* interval is slightly prolonged. Rate = 55. April 9, 1915.

cardiac weakness. On Nov. 28, 1914, an electrocardiogram showed normal rhythm and defective conduction in the right bundle branch. After 1.7 grams of digitalis an electrocardiogram, taken Dec. 15, 1914, showed absence of auricular activity (Fig. 3a). Atropin sulphate, gr. 1/50 subcutaneously, failed to change the electrocardiogram except for slight increase in rate. Digitalis was stopped and on Dec. 29 an electrocardiogram showed normal rhythm with *P* wave present.

CASE 3. Man of 37 years, with atrioventricular rhythm following auricular flutter, and already described in detail in a previous paper.<sup>3</sup> On two occasions, a month or more apart, the auricular deflections were made to disappear from all three leads of the electrocardiogram by courses of digitalis (2.0

grams in a week), as shown in one instance in Fig. 4a (Feb. 23, 1915). There was no evidence of fibrillation. He had shown a characteristic fibrillation record on a previous occasion during the transition from auricular flutter to the atrioventricular rhythm. On still a third occasion, after digitalis, a large number of the ventricular complexes were unattended by auricular deflections; those that were accompanied by them showed a marked delay in backward conduction across the auriculo-nodal junction (long *R-P* interval). In this case the sino-auricular node was not functioning and digitalis apparently blocked off the auricle from the atrioventricular pacemaker. An electrocardiogram, showing the return of the auricular deflections in the atrioventricular rhythm, is given in Fig. 4b.

FIG. 2.—Polygrams of G. H. A.

- a. Taken March 11, 1915, showing no *a* wave in the jugular pulse. Time interval = 0.2 second.  
 b. Taken March 21, 1915, showing *a* waves occurring regularly with slightly prolonged *a-c* intervals.  
 c. Taken March 23, 1915, showing ventricular escape. The *a* falls sometimes with the *c* wave and sometimes with the *v* wave. Confirmed by electrocardiogram.

FIG. 3.

- a. The three electrocardiographic leads of W. J. B. Dec. 15, 1914, with no evidence of *P* waves.  
 b. Lead II of electrocardiogram of W. J. B. Dec. 29, 1914, showing *P* waves. (Revised.)

FIG. 4.

- a. The three electrocardiographic leads of W. S., showing no P wave, Feb. 23, 1915. Rate = 37.  
 b. Electrocardiogram of W. S., showing atrioventricular rhythm with inverted P following the ventricular complex. Rate = 42.

## SUMMARY.

Three cases of heart disease are described in which electrocardiographic evidence of auricular activity was abolished by digitalis. As soon as the effects of the digitalis had worn off, the auricular deflections reappeared. This is a rare result of digitalis administration.

## Society Reports.

### NEW ENGLAND PEDIATRIC SOCIETY.

MEETING of February 4, 1916, was held at the Boston Medical Library. The President, Dr. A. C. Eastman of Springfield, Mass., was in the chair.

The following papers were read:—

1. Fractures of the Elbow in Children\* (lantern slides). W. E. Ladd, M. D., Boston.
2. Physical Types—Dietary Control and Preventive Medicine. John Bryant, M.D., Boston.
3. D'Espine's Sign in Children. John Lovett Morse, M.D., Boston.

#### DISCUSSION.

DR. GREGG (Dr. Bryant's paper): There are few types of disease that we come in contact with in which inheritance plays a greater part than it does in mental and nervous diseases. When we talk of mental and nervous diseases we are on pretty thin ice regarding making any distinction between the two classes. We often speak of some patients as being only "nervous," and where the line is to be drawn between nervous and mental is a very difficult problem.

Analysis of cases has shown that neurotic individuals may bear children who develop manic-depressive insanity; individuals of a manic-depressive type may bear children who develop dementia precox, and dementia precox cases may bear feeble-minded children. In other words, individuals of one type of disease tend to beget offspring afflicted with a more serious type of disease. How much diet and gastro-intestinal abnormalities are to be considered as etiological factors in these different conditions I do not know. But if there is anything along the line of rectifying diet, or improving gastro-intestinal abnormalities which can be done to lessen the incidence of psychoneurotic or more serious mental conditions, we certainly ought to investigate the matter.

I tried some time ago to follow up Dr. Bryant's idea to see if there is anything in the theory that general paresis were individuals of a particular type infected with syphilis, while those who develop skin and visceral syphilis were of another type. The statistics did not come out in the analysis with great clarity, but what conclusion could be drawn suggested that you need a special type of individual in order to get general paralysis from spirochete infection.

DR. MORSE (Dr. Bryant's paper—first question): Dr. Bryant has referred to exercises which favor the development of the herbivorous type in children. I should like to know what exercises he would recommend to make the large intestine grow?

DR. BRYANT (replying to Dr. Morse): "Type" includes not only the intestine, but body form. There is no exercise that I know of that will directly change the length of the intestines, except perhaps the exercise they get in propelling bulky food, but there are exercises which will change the body form, and this is one step in the desired direction. You can enlarge the upper abdomen or lower thorax very easily, and then have present one characteristic found in the wide type, and that certainly is one factor in allowing room for the growth

of all organs. One reason for the contracted thorax in the thin type is that there is, so to speak, nothing in their upper abdomen, and there is no reason why there should be a large thorax, if on account of poses the abdominal contents are largely in the lower belly.

DR. BRYANT (answering Dr. Talbot): There is no hard and fast method of differentiating between cause and effect in this study of type, but I think type is a factor which, if used with other things, throws some light on this question. In answer to Dr. Talbot, I would suggest that improper diet, by which I mean feeding the carnivore large quantities of starch, does, of course, easily produce distention. These people have apparently a thin intestinal wall with limited musculature, and I suppose it may be for this reason that an equal amount of starch produces less distention in the more strongly built or herbivorous person. The distention of the abdomen in childhood is probably due largely to gas formation, acting upon a congenital condition, whereas in later life the pendulous abdomen of the heavy person is almost certainly acquired, and due chiefly to overeating and relaxation of the belly wall. But considering only the congenital type, you will find as many of them with poses as you do in late life. There is a very small increase. I have not looked up my records on them for two or three years, but I think there are over 60% of demonstrable poses at birth, and about 75% in the adult. I think, however, that Dr. Talbot's question concerns both ends of the proposition,—the original form you start with, and an improper diet acting upon the weak intestine apart from any possible influence of such an actual disease as rickets.

DR. HILL (Dr. Bryant's paper): I should like to ask Dr. Bryant if there is any real evidence to show that the carnivorous type actually does eat too much protein food, and if the food supply has been investigated in these types?

DR. BRYANT (after Dr. Hill's question): A great deal of work has been done on the relation of meat diet to body type and intestinal conditions, and there is no doubt that in the carnivores among whom predominate pathologic kinks, excessive putrefaction easily occurs. Patients and others of this thin type have volunteered the information that in order to get any work out of themselves they have to eat meat. I have in mind at present a newspaper reporter who told me that although it did not matter much through the work what he ate, if he had any special important assignment, he had to have at least a pound or one and one-half pounds of beefsteak to "work on." Of course this is a casual remark and is not scientific, as nine people out of ten like meat when they can get it, but I think if you inquire among extremely thin people you will find that many more than half of them prefer a high meat diet because they cannot eat other foods with comfort or satisfaction. Many have fat and starch indigestion, and it is a very simple matter in these people to cut out the bulk of the starchy foods and increase their comfort accordingly by rearranging their diet.

DR. MORSE (Dr. Bryant's paper): Dr. Morse's second question: Suppose you have a child definitely of the carnivorous type. As I understand it, you think that the carnivorous type would thrive better on a carnivorous food. Now, also, you think it better for a people to be of the herbivorous rather than of the carnivorous type. Therefore, would

\* See J. PRINCE, page 220.

you feed such a child largely on a meat diet to favor its own digestion, or on the other sort of food to change its type?

DR. BRYANT (in closing, in answer to Dr. Morse's query about feeding the different type children): You have some ten or twelve years in which to study the child, so it is not a very difficult or acute problem. In many intestines of these carnivores angulations occur which favor putrefaction. There is one thing I might suggest in relation to Dr. Morse's remarks and that is, that although you might wish to feed an individual meat from your judgment of his type, if he has a sufficient amount of kinks, he will be unable to eat his meat continuously on account of recurrent putrefaction. I have found that many of these thin people who want meat and look as if they ought to thrive on it, can perhaps eat it for a day or two at a time without showing toxic effects. Then give them vegetables over a period sufficient to allow the intestine to get cleared out, and they can go back to their meat again, and thrive on this alternating diet. On the other hand, assuming a normal intestine, one may try to increase the amount of fibrous material in the diet to the limit of toleration for a year, or more, perhaps two years, thus forcing the intestine slowly to handle a more and more herbivorous diet. It certainly will be difficult, because most of these children do not like that kind of food. I think these are the children who are incessantly asking for meat. This certainly is not the question in a younger child, in whom adaptation to diet should be more simple. The apparent inconsistency inferred by Dr. Morse's question is easily explained. It is not desired to lose the good qualities of the carnivore, but merely to prevent his too extreme development, which does tend to make him undesirable. It is, after all, a question of common sense and long persistence with a definite object in view. My protest is really against the present method of letting the child choose its own food without thought of discipline or of the future, and of course the poor follow, when possible, the example of the rich in the matter of meat and eggs for the child.

DR. SMITH (Dr. Morse's paper): I should like to ask Dr. Morse whether he considers a positive D'Espiné's sign below the seventh cervical vertebra, if it is the only abnormal sign present, if that alone is considered sufficient evidence of enlarged bronchial glands, or whether there must be with it some other evidence?

DR. MORSE (replying to Dr. Smith's question): I would consider that that was sufficient evidence to show that there was some tissue between the trachea and bronchi and vertebral column which ought not to be there. In all probability that tissue would be enlargement of the bronchial glands.

#### SPINAL INFANTILE PARALYSIS.

DR. CHARLES K. MILLS. Experience with spinal infantile paralysis points to the fact that the disease is infectious or microbic in origin and tends to spread by at least two methods: through certain occult atmospheric or climatic influences, and by contagion. The healthy children of a family should be removed to other neighborhoods, while the sick are quarantined. Through the work of Flexner and others we know the measures which should be taken to prevent the spread of the disease by the secretions of the naso-pharynx and the intestinal excretions. Good nursing plays a large rôle in the treatment of infantile paralysis in all periods of the disease. Rest of body and mind is in the highest degree important. The virtue of a quiet and composed manner should be remembered by the nurse and enforced by the physician. Light and sound should be excluded during the acute febrile stage; also insect life. The method of handling the patient counts for much, especially in cases in which meningeal irritation or inflammation is prominent. The closest attention should be paid to keeping clean the nose and throat by gentle spraying with solutions of hydrogen peroxide or other germicidal solutions. Attention should also be paid to the intestinal excretions. With the appearance of paralysis and contractures, the limbs should be kept in positions less liable to lead to subsequent deformities. Massage should not be used until the fever has largely disappeared; at first, simply as gentle stroking, and later, moderate kneading combined with the stroking. The patient should not be lifted out of the bed, its position being changed in the bed instead. A typical case of the disease is easy of recognition within three or four days after the onset of fever. It should be suspected before the paresis or paralysis appears. The presence or absence of pain and hyperaesthesia may be of value in determining whether the lesion is closely limited to the spinal cord or higher regions of the neuraxis or whether meningeal implications are shown. The physician should not make the mistake of supposing he is dealing with simple meningitis or neuritis when the fundamental disorder is poliomyelitis. When poliomyelitis is rife in more or less distant communities, one of the most essential things to remember is the frequent existence of abortive and aberrant cases so atypical as to make their nature doubtful. Such cases are as much a source of danger to others as those in which the disease is full-fledged in its manifestations. As a neurologist my attention has been called in a striking manner to mistakes of diagnosis in severe cases of poliomyelitis, especially those showing bulbar, cerebellar or cerebral lesions. I have seen in consultation cases in which the diagnosis of brain tumor or meningitis has been made. I would emphasize, therefore, that during the prevalence of poliomyelitis, patients presenting cerebral, bulbar or cerebello-bulbar symptoms should be closely scrutinized with the idea that they may be cases of poliomyelitis of unusual localization. Unless the physician is aware that in the aberrant types the disease may attack practically any part of the brain or cord, he is likely to be misled in diagnosis. Instead of the physician being misled by abortive cases of mild type, exactly the opposite may occur and he may be confronted with febrile symptoms of the most severe character. In three such cases the condition was taken to be

#### SYMPOSIUM ON POLIOMYELITIS.

A JOINT MEETING under the auspices of the Department of Public Health and Charities of Philadelphia, the Philadelphia County Medical Society, and the Philadelphia Pediatric Society, to discuss anterior poliomyelitis, was held on Thursday, July 13, 1916, at 8.30 p.m., at the College of Physicians of Philadelphia. DR. JOHN D. McLEAN, President, Philadelphia County Medical Society, presiding.

cerebro-spinal meningitis, tumor or abscess; in two instances, typhoid fever of the cerebral type. Bearing in mind, therefore, the abortive form on the one hand and that of overwhelming severity on the other, the physician will be on guard concerning diagnosis, prognosis and treatment. The disease prevails epidemically in June, July, August and September. Whenever possible, children of an infected community, who presumably have not been infected, should be removed to locations supposedly immune; and, children should not at once be mixed with others who have been brought from a region where the disease had not existed. The manifest precaution is, whenever possible, to take great care in isolating children from a locality in which the disease is epidemic until the period of incubation is over, that is, after two or three weeks have elapsed.

#### ANTERIOR POLIOMYELITIS.

DR. JAMES H. MCKEE: As Dr. Mills has said, Philadelphia has splendid traditions in the treatment of epidemics. There is little that is characteristic about the onset of poliomyelitis; so very many of the symptoms simulate those of other infections and of some autointoxications. There is nothing very typical about sudden onset with moderate fever usually lasting for several days; nor is there anything very characteristic about the constitutional symptoms, or the fact that the attacks sometimes follow infectious disease. This is particularly true of the polio-encephalitis types. Yet we doubt not that the nervous symptomatology is suggestive in the presence of epidemics. It is not usual for babies and very young children to have severe pains in legs, arms, fingers and toes; headache and backache. This is also true of the tenderness which is often quite general and the rigidity of the neck. There are relatively few things in early life that cause such symptoms and signs. I need not say that we should seek light from the laboratory, where the results of blood and spinal fluid examinations are of undisputed value. One other symptom that is uncommon in infancy and early childhood and which so often leads to the diagnosis of "rheumatism" is that of profuse sweating. In the differential diagnosis we must consider scurvy, but that is a chronic affection with slow onset and definite history and is usually afebrile. Tonsillitis in early life may be accompanied by severe pains. In the various conditions to be considered differentially the laboratory comes to our aid. The appearance of the paralysis marks the place at which most of us should leave off with the patient and be prepared to accept a subsidiary rôle, leaving the major part of the treatment to the orthopedists who know much more about this stage than do we. In the prevention of the disease we must deal with prophylaxis in general. Since the disease occurs particularly during the hot months of the year, we should get the children out of the large cities. The patient should be segregated and much attention paid to the care of all discharges. Animals, although not infected, may be carriers, and should be excluded from the patient. Attendants should wear uniforms and probably rubber gloves. Cleansing of the nasopharynx is essential. The bowels should be opened freely; perhaps nothing is better than the old-time calomel followed by castor oil or salines or hot baths of mustard with as little disturbance of the patient as possible. Sweating is probably one of Nature's efforts to eliminate the

toxins and we have felt that this should be increased as much as might be. In the presence of meningitis lumbar puncture seems wise to reduce pressure and lessen toxicity. Great emphasis should be laid upon the necessity of absolute rest and quiet for the patient. Protection of the paralyzed parts with cotton, wire frames, etc., needs only to be mentioned. Voluntary activity should be resumed very slowly. Hope for the recovery of the paralyzed part should obtain not only for a year, but for many years.

#### POLIOMYELITIS.

DR. PAUL A. LEWIS: Six years ago in this building, before the College of Physicians of Philadelphia, I gave a summary of what up to that time had been done in the study of poliomyelitis. This summary was given from the results in the laboratory of the work of Dr. Flexner and myself. Two years ago Dr. Flexner made a statement of what he had done with other associates in the mean time. Since then little progress has been made. I can in no way disagree with anything that has been mentioned by Dr. Mills or Dr. McKee. They covered the ground accurately so far as their statements went. Perhaps you have seen the article by Dr. Flexner in the *Public Ledger* of last Sunday in which he summarizes his experiences in the matter. While there are some little corrections or notes to be made to that publication, yet so far as the laboratory work goes, it contains the latest evidence. I shall try to recall briefly my own experience with the work and emphasize some points of our laboratory findings in this and in other infectious diseases with which a community may have to deal from time to time. Poliomyelitis, as all know, is understood to be an infectious disease and, in some greater or less degree, a contagious disease. Its cause is known; to the elect few who have had opportunity to work with the disease in the laboratory its cause may be said to be well known. Reports in current newspapers of the very recent discovery of the cause of poliomyelitis are, of course, out of date. The essential cause was discovered six years ago and became a matter of common knowledge to those who read the results of work in laboratories. Three years ago, with the actual cultivation of the organism by Flexner and Noguchi, the causal organism became more perfectly known. Six years ago inoculations were made from the spinal cord of the human dead of the disease into the monkey's brain and the disease was reproduced in characteristic fashion. From the infected monkey the disease was transferred through others to many hundred, and up to the present time the series has possibly reached hundreds of actual passages. It was found very shortly afterward that the infectious material from the central nervous system of the human could be passed through filter-sufficiently small to remove the bacteria and that there would still be a fluid highly infectious. This established the fact that the micro-organisms were of well known bacteriological status, small enough to be passed through filters and difficult to see under the microscope. Some such may be bacterial in nature and can be cultivated as other bacteria are, and others are probably protozoa, such as the virus of yellow fever and transmissible only through an intermediate host. The virus of poliomyelitis seems to be of the former class. It has been said that the organism is ultramicroscopic. It can be seen, however. The organism is so small that we cannot, however, tell anything about its structure, as is now

sible with the tubercle bacillus for example. We know the cause of poliomyelitis chiefly through Flexner and his co-workers, but their experiments have been confirmed and extended by others. Much has been said about the methods of transmission. I believe the studies have indicated to a certainty that transmission is by contact. On the other hand, there may be other methods of transmission. There are certain bizarre facts in connection with the disease not easily explained on the basis of direct contact. However, we cannot go astray in taking this assumption of contact as the starting-point of combating any epidemic that may arise. There is often difficulty in guarding against contact because many cases are abortive to the extent that the individual shows no signs which lead the family to call the physician and no sign which would lead the physician to be positive in his opinion whether the patient had been suffering from any infection, to say nothing about poliomyelitis. For a certain number of paralytic cases there are a number not paralytic, and these are just as dangerous to the uninfected, as are the paralytic cases. Upon these practical matters I feel the fullest assurance that your Board of Health is fully equipped and has a spirit entirely adequate to deal with the matter when the time comes. Such a time in this city we hope may be far from us. We must recognize that the time may come when it will be necessary to exercise the utmost patience with what the health department may deem essential in the effort to combat such an epidemic. By the examination of the spinal fluid tuberculosis and meningitis can be excluded if the tubercle bacillus is found. The study of the epidemiology of the disease under certain conditions the laboratory can greatly help. The laboratory, however, has done its best work in showing that individuals in contact with the infected are frequently carriers of the disease. The laboratory has confirmed the clinical observation that there is a mild abortive or subparalytic form of the disease. Furthermore, the presence of the virus in the nasal secretions has been demonstrated. There is no doubt that healthy adults may carry the virus if they are in contact with the infected individual. I want to emphasize the fact that we are on the right track so far as the laboratory can show in any prophylactic measures which the department of health may think necessary, based upon the supposition of the contagiousness of the disease. The laboratory has produced nothing of practical importance in the therapeutic control of the disease, beyond the fact that certain experiments by Flexner and his co-workers show that the serum of immunized animals and some chemicals could under certain conditions mitigate the disease in monkeys. On the other hand, the fact that these workers have not shared their work with the public is sufficient evidence that they have not a cure for poliomyelitis. Anything the newspapers may say to the contrary should not excite anybody. In considering our ability as a city to cope with this disease we find that we have a good health department and a well educated medical public. That which we have not got, but which could be used to great advantage, is an available sum of money to be devoted to the study of infectious diseases.

#### INFANTILE PARALYSIS.

DR. J. TORRANCE RUGH: The treatment of the ravages of infantile paralysis devolves ultimately

upon the orthopedic surgeon. There are, however, many things which the general practitioner should know regarding the care of these patients during and following the attack. The great essential in the after-treatment of these cases is absolute rest. You will be importuned by the family to allow the patient to sit up, or to move the affected leg or arm. Don't let it be moved; keep that part still, at absolute rest! The treatment as advocated by Oppenheim and elaborated by Lange of fixation in plaster of Paris to secure rest, essential for restoration of function and the carrying away of the products of the inflammation, has given by far the best results in these cases. The great trouble, however, is the difficulty in securing the cooperation of the family in allowing such fixation. Any treatment, so far as our experience goes, which is directed to the nerve centers themselves, has met with utter failure. Certain electro-theraputists claim ability to restore to a very much greater degree the nerve function of these nerve centers than can be accomplished by any other means. But here enters the great problem to which Dr. Mills has already called attention,—that in all grades of infection from the abortive to the fulminating, no man living knows how far recovery of paralysis will take place without any aid whatsoever. Some of these cases which have been totally paralyzed, recover with apparently no evidence of the disease. Therefore, to ascribe to any one method of treatment curative effects so far as the nerve centers are concerned, is entirely out of the question. Our efforts must be directed chiefly to the care of the paralyzed parts. There is a too great tendency to begin the use of massage and electricity too early. These muscles must be put at complete rest until all evidence of the acute condition has subsided. Then the tonic treatment by massage, electricity, or whatever means, are employed, should be begun in the endeavor to maintain the tone of the muscles and the life of the muscle fibers. The muscles are kept at rest to guard against any strain which tends to increase degeneration of the fibers. There must be also the prevention of faulty postures. As a result of the acute inflammation in the structures faulty postures begin extremely early, even before they show themselves to the eye or the finger of the examining surgeon. If the paralysis affects the trunk muscles, the child should not be allowed to sit up. If the paralysis affects the legs, the patient should not be allowed to walk, as there is nothing to maintain the weight of the body except the ligaments and they are insufficient, unless supported by the muscles. Therefore, when the muscles are paralyzed the earliest thing to do is to keep the parts absolutely at rest; keep them from assuming a deformed position and guard them against strain. When the child begins to walk the extremities should be maintained in their proper position. It is surprising, in many instances, the great amount of power which will return after four or five years when these muscles which have been subjected to constant strain have been protected and the part maintained in proper position. If there is any tendency to deviation from the normal position a brace should be applied to the part. The indications for the application of braces are definite, whatever condition may be present and no brace should be applied, except to accomplish certain absolute needs. The therapeutics of a brace are as accurate as those of a drug. Another measure of value to be employed early is that of having the patient practise voluntary movement of those muscles which have

not been totally paralyzed. By giving the child voluntary control over a group of weakened muscles the opposing muscles will be prevented from drawing the part into a deformed position, and when the child walks he will be able to maintain the correct position. In those cases in which there is total loss of power, operation offers a great deal in treatment. This, however, brings in a portion of the work which belongs to the specialist, and any man who attempts work of this kind, unless he is trained to it, will meet with absolute defeat in the treatment of these cases. The surgical treatment of infantile paralysis is divided into the two great classes of destructive and constructive surgery. Constructive surgery is indicated after two years have elapsed since the attack of the paralysis, and consists chiefly in the transposition of tendons, silk inserts and similar measures. Destructive surgery, which aims at securing stability at the expense of certain structures or functions, should not be employed until six years have passed, and in the selection of operations those which utilize structures already existing are to be preferred to those which make use of foreign substances for various purposes.

DR. WILMER KRUSEN, Director of Public Health and Charities, Philadelphia: Of the two cases of reported infantile paralysis now in the Municipal Hospital, one is a case of true infantile paralysis; the other, a case of infantile paralysis, but not of the poliomyelitic type. We have found that the child's paralysis is due to a cerebral abscess following middle ear disease. We have, therefore, only one case of true infantile paralysis. You can readily understand that with such a severe epidemic in New York and Brooklyn, our work in connection with the department of health has been most aggressive. While we believe in preparation for a possible epidemic, we do not believe it wise to frighten either the public or the profession. We have wards available in the Municipal Hospital to take care of at least 100 cases. If necessary, it will be possible to have other general hospitals set aside certain space. I want to take this opportunity to thank the pediatricists, neurologists and orthopedists and all others who have given of their time and service in the last few weeks in assistance to the Department of Health. We have been trying to educate the family to send for the physician promptly when illness occurs among the children. We shall pursue in poliomyelitis the same stringent measures observed in cases of smallpox.

DR. JOHN F. SINCLAIR, President, Philadelphia Pediatric Society: I am glad that for the present the misfortune of an epidemic of infantile paralysis has not come to us. It seems imperative, however, that we should be alive to the questions connected with this disease and be prepared to meet it if we must. Personally, I want to thank those who have been so ready to coöperate, the many who have shown their interest in the subject by the large attendance at this meeting, the College of Physicians for giving us the use of this room, as well as the essayists of the evening.

DR. D. BRADEN KYLE laid emphasis upon the responsibility of the upper respiratory tract for the infection and spoke upon prophylaxis and treatment from this standpoint.

DR. CHARLES K. MILLS: We are not yet aware of the manner in which poliomyelitis is transferred from one geographical locality to another; we see it appearing in widely different sections with great

intermediary regions free of the disease. In the migration of the contagion I think not enough attention has been paid to the part played by animals and to the birds of the air. The possibilities in this connection offer fascinating subjects for study.

## Book Reviews.

*Treatment of Infantile Paralysis.* By ROBERT W. LOVETT, M.D., Boston. Philadelphia, P. Blakiston's Son and Company, 1916.

There could hardly be a more opportune time for the appearance of this work by one of the leaders of American orthopedics than the present juncture, when anterior poliomyelitis is acutely epidemic in New York City and elsewhere in the United States. The great prevalence of the disease in this country since 1907 has led to its more intensive study here than in Europe, and it is to American internists, orthopedists, and laboratory workers that we are indebted for the greater part of our knowledge of its pathology and treatment. Naturally, Dr. Lovett is chiefly concerned with the treatment of the convalescent and chronic phases of the disease, and his chapters on these subjects represent the ripened surgical experience, based on the unusually extensive opportunity of observation which he has had. The earlier chapters, however, on the pathology, symptoms, types, epidemiology, diagnosis, and prognosis of poliomyelitis, and of the treatment of its acute phase, are likewise of extreme value and summarize in classic form the best of our present knowledge. The chapter on muscle training describes a series of valuable exercises designed for the reëducation of infantile paralytics, in which the author acknowledges the valuable contribution of his assistant, Miss Wilhelmine G. Wright. The closing chapter describes the employment of the spring balance muscle test devised by Dr. E. G. Martin, and first applied by him in 1915. Not only at the present time, but in the future, this monograph must be one of extreme interest and value to general practitioners, surgeons and medical students.

*The Medical Clinics of Chicago.* W. B. Saunders Co., Philadelphia, March, 1916.

The March number of the *Medical Clinics* contains a large variety of case reports by seven internists. The cases cover a wide range and there is much incidental valuable information brought out in the discussion. In this number is introduced an account of the further progress of a case reported in the first number. If this feature is continued and developed so as to give the actual end results of all the cases discussed it will greatly enhance the value of the *Clinics*.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.50 per year for all foreign countries belonging to the Postal Union.

An editor will be in the editorial office daily, except Sunday, from twelve to one-thirty p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to:

ERNEST GREGORY, *Manager.*

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

## PREVENTION AND TREATMENT OF POLIOMYELITIS.

THE epidemics of poliomyelitis of New York City and elsewhere continue apparently unabated. On August 10, the number of cases in New York City reached a total of 5822 with 1298 deaths. In New York State, outside of New York City, the total of cases on this date was 856 with 79 deaths. In Massachusetts the total number of cases since June 1 is 178, with 19 deaths. It is evident that the percentage mortality in this commonwealth has been considerably lower than that in New York.

Naturally, the prevention and the treatment of the disease are topics which receive primary attention. Rigorous quarantine regulations against New York City have been adopted by many of the surrounding states. In a recent weekly report of the U. S. Public Health Service is published the following standard set of reasonable quarantine regulations as drawn up originally by the Vermont State Board of Health and recommended for adoption elsewhere.

"1. No child under the age of 15 years shall reside in this state for a period of more than 24 hours without being reported by an attendant, parent or guardian, to the health officer of the town or city where such child is, provided such child has been in the City of Greater New York, since the 20th of June, 1916.

2. It shall be the duty of every housekeeper, manager or proprietor of every hotel or boarding house where such child is domiciled immediately to report such child, giving the name and age, to the health officer of his city or town.

3. Every such child shall be subjected to quarantine for a period of two weeks from the time such child was last in the City of Greater New York.

4. The Health Officer of every town and city to whom such a child is reported shall immediately serve a written notice upon the head of the family in which such child is. This written notice shall contain a copy of these regulations and an order signed by such health officer requiring such child to remain on the premises in which it is at that time for the specified time of two weeks after last leaving the City of Greater New York.

5. Each health officer to whom such a child is reported shall require of the attendant, parent, or guardian of such child a certificate in writing, duly signed by a legal practitioner of medicine, certifying that the nose and throat of such child has been thoroughly washed with a solution of a teaspoonful of common salt in a pint of water once a day for a period of three consecutive days before the premises are released from quarantine.

6. No child under 15 years of age shall enter any house so quarantined.

7. A placard containing the word 'quarantine' shall be sufficient evidence to all persons that the premises are quarantined for the purpose of these regulations.

Nothing in these regulations shall be construed to prevent other members of a household in which there is a child as above described, who has left the City of New York since June 20th, 1916, from attending to their usual occupations.

The owners, managers, or proprietors of hotels and boarding houses may place no restrictions on attendants or guests in their hotels or boarding houses further than the strict isolation of any children, as above described, from New York City, provided such children are isolated to the satisfaction of the local health officer, and their noses and throats irrigated as specified.

Each health officer will see that a copy of these regulations with which he is furnished is conspicuously displayed in at least three public places in his town or city.

These rules and regulations will remain in force until further notice."

Many medical journals are publishing special poliomyelitis numbers, and a large amount of literary material is thus being produced and accumulated on this subject. Various suggestions have been made with reference to the specific prevention of the disease in individuals. In this connection we would call particular attention to the suggestion made in an article by Dr. Whittemore in another column of this issue of the JOURNAL, and to other suggested preventive measures, described under the Miscellaneous column of our present issue. Naturally, the determination of the value of these suggestions must rest upon repeated and extensive experimental observations of their efficacy. Attention is also called to abstracts of current literature on poliomyelitis, to the Philadelphia Poliomyelitis Symposium, and to a review of Dr. Lovett's recently published monograph on the subject in other columns of this issue of the JOURNAL.

Numerous suggestions have also been made relative to the treatment of the disease. Most noteworthy among these is that of Dr. S. J. Meltzer of the Rockefeller Institute, who urges the use of intraspinal injections of adrenalin; and that of Dr. N. MacL. Whittaker of Brooklyn, who has reported beneficial results from the hypodermic injections of quinine and urea hydrochloride.

The conference of pathologists and internists which was held at the New York Academy of Medicine on August 3 and 4, resulted in the appointment of two subcommittees between which the work to be undertaken will be divided. The first committee, which is to consider all phases of laboratory investigation and to suggest subjects and lines of study in connection with poliomyelitis, consists of Dr. Simon Flexner of the Rockefeller Institute as chairman, and the following members: Professor Ludwig Hektoen, University of Chicago; Professor Hans Zinsser, College of Physicians and Surgeons; Professor R. M. Pearee, University of Pennsylvania; Professor J. W. Jobling, Vanderbilt University; Dr. G. W. McCoy, director of the hygienic laboratory at Washington, and Dr. Theobald Smith, Rockefeller Institute.

The other committee, which will consider practical measures that might apply in the suppression of the epidemic, is made up of Professor Victor C. Vaughan, University of Michigan, chairman; Professor M. J. Rosenau, Harvard; Dr. William H. Park, Department of Health;

Dr. F. W. Peabody, Boston; Dr. John Howland, Johns Hopkins University; Dr. Augustus Wadsworth, director of the State Laboratories, and Professor C. C. Bass, Tulane University.

It was also announced on August 7, by Dr. Haven Emerson, New York Health Commissioner, that a committee of entomologists, connected with the U. S. Public Health Service, has been appointed to undertake an investigation of all forms of insect life to be observed in New York City and vicinity, with a view to determining what species, if any, can or may be carriers of poliomyelitis infection. The likelihood of insect transmission of disease has of late been largely discredited. The work of Rosenau in 1912 remains uncontroverted, however, and the possibility of this mode of infection should still be seriously considered. The etiology is rendered fairly certain by the work of Flexner, and seems without reasonable doubt to be represented by the minute coccus-like organisms which he originally observed and described.

The seriousness of the present epidemics seems rather to increase than diminish. The prevalence of poliomyelitis is by far the most important outstanding medical phenomenon in the United States today. Doubtless the disease will, in time, run its course like all self limited epidemics. Meanwhile everything known to science that can be done to check its extension is being carried out. It is the relative limitation of our knowledge with regard to the disease, and our lack of specific methods of prevention and cure, which lessen our present control of its spread, and make the subjects of prevention and treatment the most important present aspects of the situation.

## TWO PHYSICIANS OF A FORMER GENERATION.

IN the issue of the JOURNAL for April 22, 1915 (Vol. clxxii, p. 603) we commented editorially on the life and on the editorial and medical writings of Dr. William Wallace Morland, an early editor of the JOURNAL, basing our comment on material contributed by a correspondent. This same correspondent has recently sent to the JOURNAL some hitherto unpublished verses addressed by Dr. Morland to his classmate, William Thornton Parker.

Dr. Morland received the degree of A.B. from Dartmouth in 1848, and D. O. in 1851.

classmate, Parker, who was evidently his intimate companion and friend, entered the Harvard Medical School together, and both received from it the degree of M.D. in 1841. Dr. Parker died on March 12, 1855, the year in which Dr. Morland first became associated with the JOURNAL as assistant to the editor, Dr. J. V. C. Smith. Dr. Parker's obituary was published in the issue of the JOURNAL for March 22, 1855 (Vol. lii, p. 144). Though there is no positive evidence on the subject, it seems probable that it was written by Dr. Morland. The following extract affords interesting testimony, not only to Dr. Parker's qualities of character and mind, but to the esteem in which he was held by his lifelong friend:

"By the death of Dr. Parker, both the profession and the community have sustained a real loss. To eminent professional abilities, he added that sound judgment, highly honorable feeling and exceeding kindness of heart, which, united, constitute the truly 'good physician.' From early and most intimate acquaintance with him we feel that we can speak with confidence of his attainments, his exertions for usefulness, his qualities of heart and mind. For many years 'we have been friends together,' and the sadness which the departure of a valued associate brings with it is mingled with an unusual amount of very grateful and pleasant reminiscence. Active and industrious in his habits, Dr. Parker established an extensive practice for himself, in South Boston, immediately after taking his medical degree. There are many in that portion of our city who can testify to his unflinching integrity, his entire devotion to the interests of those entrusted to his medical care, his acute discrimination of disease, and his faithfulness, to the very last of his career, as a practitioner. To this trait, indeed, is much of his ill health, latterly, to be ascribed. Overwork did a vast deal towards developing the slow but sure disease of which he died. Unwilling to yield, he struggled on, visiting his patients continuously, often leaving his bed for several successive nights when ill able so to do. Compelled at last to quit an excellent practice and to resign the home-comforts his industry had gathered, he sought health both in Cuba and by a residence of some months in Europe, but without avail. With a strong will and a large share of the good spirits which once animated him, he toiled almost to the last day of his life, to supply the failure of the means formerly afforded by his professional exertions. Occupation was his life. He never seemed unhappy when employed. Pleasantly retired in a beautiful neighboring town, he wrought with pen and pencil, amid much physical trial, but

surrounded with warm friends and delightful influences. To most of his medical brethren here, his skill as an artist is well known. We do not know, in the ranks of the profession, any one who at all approached him in the art of delineation and design. In pencil drawing he was an adept; in coloring, his hand was unrivalled. We have seen his copies from the most splendid anatomical plates, which we literally prefer to the original. In sketching, as well as in copying, he was peculiarly felicitous. One of the most touching circumstances connected with our remarks upon this accomplishment is the fact that the *last* work done by his hand was executed for the writer of this slight tribute to his worth. These drawings, finished only a few days before his death, have a value that can attach to such works alone. He who would so use the pencil might find in it almost a support. By a medical man, especially in these days of minute investigation, the talent cannot be too highly estimated.

"Constantly occupied through the past winter, and enjoying much of that social comfort which was ever grateful to him, he has at last gently passed from earth, solaced by the consolations and hopes of religion. Violent hemorrhage from the lungs was the final agent in the gradual process of dissolution."

The following lines, to which we have previously alluded, further represent in verse Dr. Morland's feeling for his friend and afford evidence, likewise, of his literary ability in metrical composition:

#### TO MY CLASSMATE

WILLIAM THORNTON PARKER (A.M., M.D.)

July, 1838.

There is a word, alas how often spoken,  
A startling word  
Telling of tender ties that must be broken  
When it is heard:  
Farewell! Oh whether in life's early morn  
Or closing day,  
Some friends asunder by that breath are torn:  
How hard it is to say!  
And why is it so hard?—we surely know  
That here below,  
Life's golden current cannot smoothly flow,  
That thorns will grow  
Upon the rose that woos our eager grasp,  
And chillily grow  
The hands once joined in fervent clasp,  
Oh, this we know!  
I could bid thee farewell—and if again  
We meet,—  
Grant heaven it may not be with stifled pain  
To greet,—  
I wish not that a change should darkly fall  
Upon our youth,  
That cold Deceit with her enshrouding pall  
Bury Love's truth.  
Oh, this can never change the low-breathed tone  
Saying farewell!  
It hath a moving power all its own  
Its tale to tell.  
The tongue may falter, but the speaking eye  
How eloquent!

While freshly glow the tints in memory's sky  
 With future bodings blent.  
 Once more, my friend, farewell!—now all is bright  
 Our path around.  
 May fortune kindly for thee ever light  
 Her torch!—and bound  
 About thy brow be Fame's well-chosen wreath;  
 And when all thickly comes thy laboring breath,  
 And droops thine eye,  
 May Hope with lifted finger point above,  
 And show thy seat amid the throngs that love  
 To die  
 Such death as makes the Christian's cheerful tongue  
 In tones triumphant on the death-air flung,  
 Bid earth farewell!

### MEDICAL NOTES.

**CHEMISTS AND TECHNICAL MEN TO MEET IN NEW YORK.**—Official announcement of the meeting of the American Chemical Society, to be held in New York September 25 to 30, in conjunction with the Second National Exposition of Chemical Industries, was issued to the members by Dr. Charles L. Parsons, secretary, on August 15. Dr. Charles H. Herty, of the University of North Carolina, president of the American Chemical Society, will open the exposition on Monday, September 25, at 2 o'clock in the afternoon, with an address reviewing the history of chemistry and the chemical industries in this country, and outlining developments since the outbreak of war in Europe. The presidents of coöperating societies, such as the American Electrochemical Society, the American Institute of Mining Engineers, and the American Paper and Pulp Association, will follow Dr. Herty with speeches of welcome and reviewing the progress made in the industries represented by them.

The first general session of the American Chemical Society will open at Columbia University on Tuesday morning, September 26, and arrangements are being perfected for a public meeting in the large hall of the College of the City of New York on Tuesday afternoon, when addresses will be made of general public interest pertaining to the interesting developments in the field of applied chemistry during recent years.

The program of the week's meetings will provide for general conferences on subjects in which the chemists of the country are now interested, and it is intended that the lecture hall of the Grand Central Palace and Rumford Hall in the Chemists' Club building will be occupied each afternoon at the same time by one or other of the different divisions of the society for the discussion of such industrial topics as the production of dyestuffs, medicinal chemicals, industrial alcohol, the manufacture of paper pulp and by-products, oils and motor fuels, glassware and porcelain, steel alloy metals, new developments in chemical industries, etc.

On Wednesday and Thursday mornings a general symposium on colloids will be held, theoretical considerations being discussed on the first day and the industrial applications of colloid chemistry on the second day.

The American Electrochemical Society has planned a series of interesting meetings. The electrochemical group will open its meeting later in the week, on Thursday, September 28, with a technical session devoted to a review of American progress in the electrochemical industry. A complimentary smoker will be held on Thursday evening, and on Friday evening there will be a joint banquet at the Waldorf-Astoria of the members of the American Chemical Society, the American Electrochemical Society, and the Technical Association of the Pulp and Paper Industry.

### EUROPEAN WAR NOTES.

**SHIPMENT OF RED CROSS SUPPLIES TO GERMANY.**—It may be recalled that during the past winter, as noted in the JOURNAL at the time, the British Government refused to permit hospital supplies to be sent from the United States to the Central European Powers, on the ground that there was no American Red Cross body in those countries to receive and use them. In reply to this action, former President Taft, chairman of the central committee of the American Red Cross, wrote, on May 8, to the United States Secretary of State, commenting as follows on the British proposition to admit no medical stores into hostile countries except for use by an American medical or hospital unit.

"This exception amounts to no concession, for the reason that, as the British Government was advised in August last, after the first of October, for lack of funds, we were able to maintain no hospital units in any of the belligerent countries. The authorities of the American Red Cross believe that under the Geneva Convention, to which the United States and all the belligerent powers are signatories, the United States has the treaty right to insist that articles serving exclusively to aid the sick and wounded in the form of hospital supplies, shipped by the American Red Cross to the Red Cross of the Central Powers, shall not be declared contraband, but shall be allowed safe conduct to their destination."

Again on June 10, Mr. Taft wrote as follows to the Secretary of State, making as a counter proposal, the suggestion that a commission be appointed to supervise the handling of American Red Cross supplies for the Central Powers.

"Replying to the letter from your Department of June 2d, relative to the question of the shipment of Red Cross supplies to the Central Powers, which was in answer to my letters of May 8th and May 27th, I beg to add the following:

"In a communication, dated March 27th, from the British Foreign Office, which was transmitted by your Department to the American Red Cross, occurred the following paragraph:

"Your Excellency will be aware from my note of the twenty-second instant that His Majesty's Government have felt obliged to withdraw the lists of articles which they previously put forward as coming within the meaning of the provisions of the declarations of London regarding articles serving exclusively to aid the sick and wounded. His Majesty's Government have recognized one general exception to the restrictions imposed on the importation of medical stores into enemy countries, namely, that any supplies sent by the American Red Cross to an American medical or hospital unit in an enemy country will be allowed to pass freely into that country so far as His Majesty's Government are concerned."

"In commenting on this in my letter of May 8th to you I said:

"Through your Department we are now in receipt of a communication from the British Government, announcing that it does not intend to permit any further shipment, unless it is a shipment to our own hospital units, in a territory of the Central Powers. This exception amounts to no concession, for the reason that, as the British Government was advised in August last, after the first of October, for lack of funds, we were able to maintain no hospital units in any of the belligerent countries."

"As a possible solution to the difference which now exists in our view of the obligation of the British Government under the Geneva Convention and its announced policy in limiting the permits for shipments of medical supplies to the Red Cross hospital units in the territory of the Central Powers, I beg to suggest, on behalf of the American Red Cross, that while we have no further funds with which to maintain medical or hospital units in the territory of the Central Powers, we should be able to send over a commission of satisfactory persons to receive our shipments and to superintend their distribution to hospitals and to supervise their use. This commission would be composed of persons for whose good faith the Red Cross would vouch in seeing to it that the supplies were devoted to hospital purposes only and to the relief of the sick and wounded."

"The Red Cross would be glad to submit the names of the persons constituting such commission to His Majesty's Government before appointing them. We have been very hopeful that the British Government would change its view as expressed in the correspondence already referred to, but if it maintains its position, we venture to make this proposal as a counter proposition, with the hope that you will submit it to the British Government on receipt of their

reply to our letter of May 8th, which, as you say in your last communication, you have already forwarded."

The following is the reply to this letter under date of July 12, by Sir Edward Grey, Secretary of State for foreign affairs of Great Britain.

"I have the honor to acknowledge receipt of Your Excellency's note of the twenty-second ultimo regarding the proposal put forward by the American Red Cross with a view to facilitate the shipment of Red Cross supplies from the United States to the Central Powers."

"I have carefully considered this proposal, but I am at a loss to understand the suggestion made by the American Red Cross and quoted in Your Excellency's note that the policy pursued by His Majesty's Government is contrary to the provisions of the Geneva Convention. His Majesty's Government have in fact always taken the most scrupulous care to observe the provisions of this Convention, and they cannot appreciate how the present subject at all falls within its scope. In this connection Your Excellency may be interested to read the annexed statement published in the *New York Times* on the 12th May last, which sets forth the views of the French Government on the claims of the American Red Cross."

"His Majesty's Government have no reason to believe that there is an absolute lack in the territory of the Central Powers of the materials required for Red Cross supplies; they have, on the contrary every reason to suppose the reverse for, to give only one instance, not long ago a medical member of the Austrian general staff, Professor Hoehenegg, wrote to —, stating that there was no shortage and no prospect of shortage in medicines or bandages, nor even in highly special medical remedies, so that Austria was hardly concerned in the success of the protest made by the American Red Cross against the obstacles placed by the Allies in the way of the export of such articles from America. In these circumstances it is evident that if any deficiencies in these supplies exist, as to which there appears to be no evidence, it must be due to the fact that the Central Powers prefer to use the materials for other purposes, and any steps that may be taken to give them further supplies would conduce, not to the increased welfare of the sick and wounded, but merely to set free larger quantities of such materials for belligerent purposes."

"His Majesty's Government do not, therefore, feel able to create such an entirely new precedent as would be constituted by the supervisory commission suggested by the American Red Cross."

As a matter of fact, there is now a Red Cross unit in Germany and it remains to be seen whether, in view of this, Great Britain will now permit the shipment of surgical supplies for its

use. In any event, it is hard to see how, as is hinted in the quotation above, medical and surgical materials could be diverted to belligerent purposes.

Finally, on Aug. 1, the following memorandum, apparently intended to close the incident, was received from Viscount, formerly Sir Edward, Grey:—

"The position of the Allied Governments in regard to the importation of medical supplies into enemy countries is that they cannot be called upon to admit a practice which has been forbidden in the case of every blockade established in the past. They consider, moreover, that the Geneva convention obviously does not apply. These principles having been settled, frequent appeals have been made to the Allied Governments to make some concessions as a matter of grace.

"One suggestion is that a neutral commission should be appointed in Germany to receive imported medical supplies and distribute them to enemy hospital organizations, but this suggestion offers no means of restricting in any way the amount of supplies imported. To meet this objection it has frequently been suggested that the Allied Governments should specify the kinds and amounts of medical supplies, the importation of which into enemy countries they will be prepared to allow. But it is impossible to fix amounts in this way. One cannot ration the whole population of Germany and Austria in drugs and bandages. No ingenuity could estimate what might reasonably be needed by the population; it is equally difficult to lay down the kind of goods which may be allowed.

"His Majesty's Government have given close consideration to the question, and they have found themselves utterly unable to evolve any system by which the general shipments of medical supplies, once permitted, could be kept within the limits at all. Their reasons for not allowing unlimited supplies to go in have been frequently stated, viz: that the material sent in would replace materials existing in enemy countries, which could, and undoubtedly would, then be applied to other, and in many cases belligerent, purposes.

"His Majesty's Government on their part have, therefore, laid down the only workable distinction they could think of, namely, that American Red Cross supplies may be sent to American Red Cross units, wherever they may be. They feel that no juster test could probably be found of the strength of humanitarian claims and the interest taken by the people of the United States in needs of the Central Empires, than the extent to which the people of the United States are prepared to subscribe money or send doctors and nurses for hospital work in Germany and Austria. Wherever the sympathies and energy of Americans are manifested by the presence of the Americans engaged in the

relief of suffering, there American supplies can be freely imported and used. This is a very definite concession and opens a wide door to American philanthropy, and His Majesty's Government cannot understand why, if feeling in the United States is strong on this subject, this door should be allowed to remain closed."

WAR RELIEF FUNDS.—On Aug. 12 the totals of the principal New England relief funds for the European War reached the following amounts:

French Wounded Fund.....	\$110,956.67
Serbian Fund.....	102,348.07
Army Huts Fund.....	74,351.60
German Fund.....	63,339.41
French Orphanage Fund...	59,377.38
Surgical Dressings Fund....	42,996.87
Italian Fund.....	21,640.54
Allies' Tobacco Fund.....	1,610.00

#### MEXICAN NOTES.

RED CROSS NURSING SERVICE.—The following announcement was authorized on Aug. 1, by former President Taft, Chairman of the Central Committee of the American Red Cross:

Under the most efficient management of Miss Jane A. Delano, Chairman of the National Committee on Nursing Service, a corps of over 7000 of the representative graduate trained nurses of the country have been enrolled for Red Cross service. This branch of the work has become so large and important and the burden of it so great that Miss Delano felt it advisable to secure a superintendent for the Nursing Bureau, to be, if possible, one of the ablest training school superintendents. The Executive Committee concurred in Miss Delano's recommendation and we are fortunate to secure for this important office Miss Clara D. Noyes, Superintendent of the Bellevue Training School of New York City, who will take up her duties with the Red Cross on or about October 1.

The appointment of Miss Noyes in no way changes the general policy of the nursing service. Miss Delano maintains her position as Chairman of the National Committee on Nursing Service, and will continue to give her invaluable assistance to the Red Cross. Thanks to her devotion, and that of many of our chief nurses who have given up their vacations to this work, more than 1000 are ready for our base hospital units alone. A large number of smaller groups, consisting of 10 nurses each, and known as "Emergency Detachments of Nurses," are also being organized to meet any possible need of the Army and Navy.

THE RED CROSS AND THE UNITED STATES ARMY.—In the issue of the *Military Surgeon* for May, 1916, is an article by Colonel J. R. Kean on the relation of the Red Cross to the United States Army Medical Corps. It is a well known fact that in the event of war the Army

Medical Corps as at present organized would be entirely inadequate for the care of the wounded except in the first zone, which consists of the first aid stations directly behind the trenches, the field hospitals and the evacuation or clearing hospitals.

"The second zone, of communications and base, employs two kinds of units—field columns, which are transporting agencies; and base hospitals, which receive and give adequate medical and surgical service to the sick and wounded. This service in our country has never been organized until war begins; and the hospital service provided has been, therefore, at the beginning of our wars inevitably deficient, untrained and unsatisfactory, and a vast amount of unnecessary suffering and loss of valuable lives has been the result.

"The third service receives the wounded and sick who are transferred from the base hospitals as they become overcrowded; and also the convalescents who are able to travel but require further medical treatment before their return to the colors. This zone includes the army general hospitals and the great civil hospitals of the country which, under arrangements with the medical department, receive and treat the sick. The French are said to have about 4000 of these hospitals, containing 600,000 beds.

"The medical service of the Army is, therefore, like a bridge of three spans, of which the first span is completed and ready for work, and the third span can be rapidly completed because the framework is already in existence. The middle span of the bridge is, however, lacking; and it is believed that the Red Cross should be the organizing agency which will complete this middle span so that the bridge will be ready for use promptly on the outbreak of war. The Red Cross fulfills this function in the Italian and Japanese services, and, to a great extent, in the German, Austro-Hungarian and other European services. It is evident that by taking up this work of organization the Red Cross will perform a public service of the highest magnitude and importance to the nation and will have in the most effective way conceivable contributed to relieve the suffering of the sick and wounded."

**MEXICAN RELIEF FUNDS.**—On Aug. 12 the totals of the principal Massachusetts relief funds for troops at the Mexican frontier reached the following amounts:

Base Hospital Fund.....	\$80,489.25
Home Relief Fund.....	2,633.00

#### BOSTON AND NEW ENGLAND.

**THE WEEK'S DEATH RATE IN BOSTON.**—During the week ending August 5, 1916, there were 202 deaths reported, with a rate of 13.85 per 1000 population, as compared with 190 and a rate of 13.24 for the corresponding week of last

year. There were 41 deaths under 1 year, as compared with 40 last year, and 46 deaths over 60 years of age, against 43 last year.

During the week the number of cases of principal reportable diseases were: diphtheria, 19; scarlet fever, 11; measles, 55; tuberculosis, 48; whooping cough, 30; typhoid fever, 2.

Included in the above were the following cases of non-residents: diphtheria, 3; tuberculosis, 2; scarlet fever, 4.

Total deaths from these diseases were: diphtheria, 3; measles, 3; pulmonary tuberculosis, 22; whooping cough, 2.

Included in the above were the following deaths of non-residents: diphtheria, 1; tuberculosis, 3.

### Miscellany.

#### FRAUDULENT INFANTILE PARALYSIS "CURES."

OFFICIALS of the Department of Agriculture, charged with the enforcement of the Food and Drugs Act, expect that the outbreak of infantile paralysis will tempt unscrupulous persons to offer for sale so-called "cures" or remedies for this dread malady. They therefore have issued special instructions to the Food and Drugs Inspectors to be particularly alert for interstate shipments or importations of medicines, the makers of which allege that they will cure or alleviate this disease, for which, at the present time, no medicinal cure is known. The officials also warn the public that any preparation put on the market and offered for sale as being effective for the treatment of infantile paralysis should be looked upon with extreme suspicion. Inspectors, accordingly, have been instructed to regard as suspicious, and to collect samples of all medicines in interstate commerce for which such claims are made. Makers of such fraudulent remedies will be vigorously prosecuted whenever the evidence warrants action under the Sherley Amendment to the Food and Drugs Act. So-called remedies for infantile paralysis which are offered for import into the country will be denied entry.

The Food and Drugs officials are particularly watchful in this instance because it has been noted in the past that whenever a serious epidemic exists, unscrupulous dealers prey upon the fear or ignorance of the public by flooding the market with worthless, hastily prepared concoctions, for which they assert curative properties, which have no foundation whatever in fact. In the present instance, inspectors already have discovered shipments of a few such mixtures.

The Department will do everything it can under Federal law to protect that portion of the public which is extremely credulous in times

of panic, and which will grasp at anything which promises protection or relief. The sale of such products at this time, the officials point out, is particularly threatening to the public health because many persons, relying on the false statements of impostors, neglect to secure competent medical advice. As a result, not only is the safety of the patient endangered, but in the absence of proper sanitary precautions, the likelihood of contagion is greatly increased.

It must be understood, however, that the Federal Food and Drugs Act applies only to products which are shipped in interstate commerce, that is, from one State to another, or which are offered for import or export, or which are manufactured or sold within a territory or the District of Columbia. Products which are made and consumed wholly within a single State are subject only to such State laws as may apply and are under the control only of State health officials. The Federal law does not apply, for instance, to patent medicines made within the State of New York and sold in New York City. Persons buying or using a "remedy" made in their own State, therefore, must rely on the protection accorded them by their local health authorities.

### PREVENTION OF POLIOMYELITIS.

THE United States Public Health Service has recently issued the following statement relative to the prevention of infantile paralysis:

"To control the present epidemic of poliomyelitis the chain of infection between persons harboring germs of the disease and the well members of the community should be broken. Infantile paralysis is probably caused by a very minute organism found in the nasal, mouth and bowel discharges of those who have the disease, or who are carriers of the germ without themselves suffering from the ailment. All of the steps in the spread of the infection are not known, but if this germ can be prevented from passing from the infected to the well person, the disease will cease.

"Infantile paralysis is not a disease of recent origin. Sporadic or scattered cases have occurred throughout the country for many years, but it is only during the last decade that the infection has assumed epidemic proportions in the United States. The present epidemic in New York City, on account of its magnitude and virulence, has awakened the residents of many communities to the danger of the importation of the disease into their own midst. This danger is real, but if due precautions are exercised it is believed that the epidemic will subside.

"The actual control of the present epidemic must be left to the City, State and Federal health authorities. These organizations will properly quarantine and care for affected per-

sons, prescribe sanitary measures, and limit as may be necessary the travel of individuals in order to protect neighboring districts from the infection. Individuals and communities, however, can do much toward their own protection.

"Poliomyelitis is probably spread, directly or indirectly, through the medium of infective secretions. Account must, therefore, be taken by communities of every means by which such secretions are disseminated. Promiscuous expectoration should be controlled. The common drinking cup affords a method for the interchange of material of this nature, and should, therefore, be abolished. Rigid cleanliness of glasses and utensils at soda fountains, in saloons and other public places, should be enforced. Flies, roaches and other vermin, by coming in contact with infective secretions, may possibly convey them to our food, and thus directly bring about the development of disease. Therefore eliminate insects. Street and house dust bear a definite relation to the spread of many infections, and it is not unreasonable to presume that they may be a factor in the dissemination of infantile paralysis. Maintain strict cleanliness of streets, yards and alleys in order to prevent the breeding of insects and other vermin. See that all garbage and waste are properly cared for and collected at regular and frequent intervals. Guard all food supplies, especially milk and other perishable products. Digestive troubles of children arising from the ingestion of food of questionable quality may lower resistance. Assemblies of children in infected localities are to be discouraged, if not actually forbidden. While the above measures are in a sense general, and applicable to many epidemic diseases, their importance should not be overlooked:

"Individual preventive measures may be thus summarized:

"Summon a physician at once and immediately notify the health officer of the presence of the disease. If the disease is present in the community, medical aid should be sought whenever a child is sick, no matter how light the illness; many cases of infantile paralysis begin with a slight indisposition. Should the illness prove to be infantile paralysis, isolate the patient, place a competent person in charge, and reduce all communication with the sick-room to a minimum. Hospital care is preferable, not only for the child, but in order better to safeguard against the spread of the disease. The sick-room should be well ventilated and screened. Nasal and mouth secretions should be received in cloths, placed in a paper bag and burned. The clothing of the child, the bed linen, and the excretions should be disinfected in the same manner as for typhoid fever, that is, by boiling, the long continued application of 5% carbolic, or other well-recognized disinfectant. The same is true for dishes and drinking vessels. Nurses should exercise the

same precautions as regards cleanliness of hands in caring for infantile paralysis patients as for those afflicted with other infectious diseases.

"A child may convey the disease to others, even after a lapse of several weeks. For this reason quarantine should be maintained for a considerable period, usually from six to eight weeks, and the above precautions should be adhered to during this time. Disinfection of the room following recovery is advisable."

## Correspondence.

### BRITISH MILITARY ORTHOPEDIC HOSPITALS.

(From Our Special Foreign Correspondent.)

LONDON, ENG., July 15, 1916.

Mr. Editor: We have passed a very interesting day in some of the Orthopedic Centres for the British forces. Thanks to the kindness of Colonel Robert Jones, we were conducted through Hammersmith Military Hospital in the morning. At the outbreak of the war the buildings now occupied by the hospital were poor house and infirmary to the surrounding district, but their equipment and size were such that the group was usually known as the "Paupers' Palace."

Patients are chosen from the various Military Base Hospitals and sent here that they may be attended by orthopedic specialists. A very interesting clinic was held and some excellent results shown, such as the efficacy of various splints to improve deformed limbs. The hospital includes a complete little gymnasium equipped with simple apparatus for the use of the convalescents. Even in some of the wards we found apparatus, such as a ladder for climbing and wheels whose resistance might be measured and controlled. With these machines and many others every opportunity is given the men to strengthen their weakened limbs. There is a large corps of massenese and also a department for exercise by electric stimulation, which was most interesting. We entered a large room equipped with about 12 beds. At each bedside sat a girl whose work it was to stimulate various motor points in the patient's muscles under the direction of the doctor in charge.

The apparatus used was not complicated. It consisted of an inductorium whose secondary coil was short and composed of thick wire. The make and break rhythm was slow. The larger of the two electrodes was led off to some convenient spot, as the back of the patient's neck or posterior aspect of the thigh. The smaller round electrode was held in the operator's left palm so that she could feel the extent of any muscular contraction caused. In her right hand she held a soft iron core which she passed in and out of the coil. The entrance of the core served to increase the current in the secondary circuit sufficiently to cause contraction of a muscle or group of muscles and the strength of stimulus could be graduated by the varying amount of core entering the coil. The doctor in charge believed the good results he was obtaining were due to the fact that he never tired the muscles out, beginning with a very brief exercise which he daily increased, and also to the fact that the rhythm of stimuli used was uniform. He demonstrated how easily he could stimulate the vastus internus which was not brought into play by simple voluntary extension of the knee joint. With the exception of ionization he made no further use

of electric currents. We passed on to see an exhibit of water color paintings. Colonel Jones had chosen, as subjects, various limb deformities resulting from wounds of long standing. The artist was a man of very considerable reputation, who was "doing his bit" in this way. Form and color were accurately reproduced and the collection will undoubtedly be of great value. A record of the most instructive deformities was being kept in plaster as well as on canvas. One room contained a well done set of plaster casts in which the maker took a just pride. Some of the casts had been made before treatment and some afterwards, while the nature of the treatment was indicated in each case so that the demonstration was most instructive.

To supplement the morning spent in Hammersmith Hospital, we paid a visit to Queen Mary's Auxiliary Hospital at Roehampton Lane. It is run by the above auxiliary with the cooperation of the medical departments of the army and navy. The unsatisfactory nature of artificial limbs which were being supplied to maimed soldiers and sailors became apparent early in the war, so that on July 20, 1915, a demonstration of artificial limbs, open to manufacturers of all nationalities was held at Roehampton House. Twenty-four different firms took part in this contest. The Directors-General of the Army and Navy Medical Services and the president of the College of Surgeons, England, with the assistance of British and Irish surgeons, acted as judges. Several American firms made very creditable showings and were given exclusive contracts for the production of artificial limbs used in connection with the work of Roehampton House. This institution undertook all such military work for the Kingdom with the assistance of a smaller hospital at Alder Hey, near Liverpool. In October last, there was a waiting list of 800 cripples. Today there is no waiting list unless it be of those in the 570 beds at Roehampton. They accept only those patients who are ready for artificial limbs, and keep them until a satisfactory degree of efficiency has been obtained with the new member. As an aid in this process and that the men may lose no time, work shops have been established on the hospital grounds. Here daily classes are held in stenography, lathe-work, woodwork, electrical fitting and automobile repair. An employment bureau undertakes to secure work for the outgoing patients, or they may go on learning their newly acquired trade in any of the larger cities of Great Britain free of charge. That is, they may enter one of the polytechnic training schools which have been established at various centres. All of the orderlies and attendants about the hospital are old patients, who constantly demonstrate to the incomers that usefulness has not gone with the loss of arm or leg.

As we entered the assembly room, the daily examination was in progress. A dozen men, wearing artificial arms, were standing in a row and each in turn demonstrated to the surgeons his proficiency with the new member. It was surprising to behold the exactness of their movements. One man, who had lost his arm at the middle of the humerus, used his good hand to close the artificial fingers about a pen and wrote his name quite legibly with the new arm. He then removed the hand at the wrist and replaced it by a fork. This he guided accurately to his mouth. Movement of the arm upward and across the chest caused simultaneous flexion of the elbow joint. Each case was considered in turn, and either passed, or the limb maker was requested to try again. A line of twenty men with artificial legs entered and each marched in turn past the surgeons. As we left the "House" and walked down the drive, the grounds were filled with cripples who hobbled about in their blue flannel suits. All that science could offer was being done for them but they were, at best, a pitiful little army of makeshift men.

Sincerely yours,

W. G. P.

## Address.

### HYGIENE OF THE MIND.\*

BY BENJAMIN P. CROFT, M.D., GREENFIELD, MASS.

THE other day while sitting at the bedside of a friend who had recently undergone an operation involving the taking of an anesthetic, I was more strongly impressed with the value of mental optimism than ever before. Here was a man well over eighty years of age, sitting in bed, recently undergoing an experience which, at its best, is a shock to one's physical or psychical makeup; and yet when I remarked that he was the best example within my knowledge "that only the good die young," he responded in kind by the retort that, "If they thought they could kill a tough specimen like me, they were very much mistaken"; and in the fifteen or more minutes of our conversation not once did he dwell upon his physical ailments except to answer questions which were the result of my interested inquiries.

This man has been a cheerful, genuine optimist ever since I have known him, and though he was well along in years at the beginning of our acquaintanceship, and I have not seen him subjected to the stresses and strains which are the usual atmosphere of the active practitioner of a profession of today, yet we know, if by no other means than from analogy, that any one who gains his financial and social competence by

catering to the public needs cannot escape such friction.

As I sat there watching the twinkling of his eyes and listening to the freely flowing and interesting ideas, I became unconscious of the wrinkled face and other signs of physical wear and tear incident to the constant use of such a long period of years; and even as we talked, I became envious of the possession of a faculty which I believe is becoming one of the most important acquisitions which we as physicians have to develop.

Now at the outset I doubt not that you would readily grant the truth of the statement that mental optimism is a very essential factor toward the prolongation of life, even though in the same breath you would look askance at any statements which tended to magnify the relative value of mind over matter, and in this I would join with you readily, because we know that in the past two decades this term, "mind over matter," as represented by one of the so-called healing sects, has been brought into such close intimacy with the medical profession that the majority of the latter have looked upon it with about the same aversion as is a red color to a bull; but because of the dislike which this term engenders in our minds, I have wondered many times of late, are we, as practitioners of medicine, not in danger of forgetting the real significance of the influence of our minds upon the successful conduct of our work and the better preservation of our physical bodies and of those who are trusted to our care.

If this subject were properly treated, I feel that it would involve a more or less to the

\* Read at the meeting of the Franklin District Medical Society, Greenfield, Mass., on March 14, 1916.

description of psychology, and this, as you know, I should feel incompetent to undertake; and besides, such a course might easily neutralize and render ineffective the few simple thoughts which I have in mind in connection with the subject elected, in so far as it applies to us as individuals in connection with our work.

Now, as usual, I can't seem to construct even a short paper without having some sort of a skeleton on which to start the foundation and superstructure, so that I find it necessary to outline a few headings under which I may develop my ideas as to what I believe are some essential factors looking toward a successful hygiene of the mental faculties.

Among the many influences which could be discussed, let me dwell for a few moments upon the following:

1. The necessity of a good control of the emotions.
2. The wisdom of periodical diversion from our usual mental occupation.
3. The value of cultivating friendship.

#### THE NECESSITY OF A GOOD CONTROL OF THE EMOTIONS.

It may be like bringing coals to Newcastle to talk to a body of physicians about the effects of the emotions as they affect disease favorably or unfavorably, and I have come to feel that in our constant efforts to cure diseases either by drugs, surgery, or both, that we are prone to forget how important the influence of a proper control of the emotions is.

It would not be very difficult to cite from the records of history the many examples or instances where sudden loss of control of the emotions resulted in exceedingly unfavorable results. Take, for example, the classical one of Vesalius, the famous anatomist, who, while dissecting the body of a woman, discovered that her heart was still feebly beating. He was so overcome by mental distress at this discovery that he suddenly dropped dead. Another classical example is that of Louis of Bourbon, who dropped dead from fright at witnessing the exhumation of his father's bones. Then there is the case of Leibnitz's niece, who, upon finding a large amount of gold under the bed of the famous philosopher after his death, had such a powerful emotion of joy that she fell dead; and this was the fate of Sophocles when he heard that one of his tragedies had been awarded the highest prize. Other cases of sudden death from excess of grief or of joy might be cited, and it is more than probable that you could give personal examples from your own experience which would add to this record.

History teaches also that loss of the emotional control, though it may not result in instant death, yet through the development of disease may have just as disastrous consequences, even though these be more prolonged. There are on record several cases of the onset of diabetes

which unquestionably were developed as the result of strong mental emotions of a depressing nature. Lorand in his book on "Old Age Deferred" cites the cases of two young women who suddenly contracted severe diabetes after a fright, while previously there had been no symptoms of such, and in the third, a case of glycosuria, it was increased very considerably; and he quotes from Professor Naunyn, who states the interesting fact that after the bombardment of Strassburg in the War of 1870 many cases of diabetes developed as a consequence of the fear and anxiety brought about by it. These examples, and many others of a similar nature, tend to support the theory that at least a certain number of cases of diabetes are the result of uncontrolled exercise of the emotions, and I judge from my reading that these untoward results are brought about by the unfavorable action of the sympathetic and vagus nerves in relation to the function of the latter in their control of the secretion and other activities of the so-called ductless glands, of which the thyroid, adrenals and pancreas are examples.

Those of you who are constantly using the blood pressure measuring apparatus have undoubtedly noticed the influence of the emotions in the raising or lowering of the blood pressure at the time of the examination, and I think that it is now definitely established that, by acting on the adrenals, mental emotions produce higher blood pressure, in consequence of the toxic action of the increased adrenal secretion, and thus favor the development of diseases of the heart and circulatory system, especially arteriosclerosis, which are so frequently sure to follow.

Then again there are well-known examples by competent observers where this same unfavorable factor acting upon the thyroid produces an alteration in the gland and the development of what we know as Graves' disease, and if this unfavorable influence is continued indefinitely, then ultimately the activity of the gland becomes changed, due to its exhaustion, and we have the development of the other disease, known as myxedema.

It is also interesting that many observers who have recently been investigating the function of the pituitary body can produce the disease known as acromegaly, and Sajous went so far as to claim that this particular gland was the central organ upon which all severe emotions reacted.

That the action of mental emotion on the sexual glands is possible is shown by the many cases of sudden menstruation after various kinds of mental shocks, and the same influence in the male could be demonstrated by citing authentic cases of impotence from the same causes.

That care, worry, grief and sorrow are able to bleach the hair and produce a characteristic haggard, worn-out appearance is pretty definitely established, and though this hair bleaching may not always occur with suddenness, as

did the classical case of Marie Autoinette of France, yet I doubt not that it occurs in a great many cases in persons less prominent than was this last-named character. I think it is safe to say that premature old age is probably brought about more frequently by the condition under discussion than by any of the other contributory causes.

The influence of the emotions in lowering the physical vitality and thus inviting attacks from disease germs has certainly a great deal of scientific interest, but I think I have cited enough examples at least to interest, if not convince you; but before leaving this phase of the matter I would like to call your attention to a few illustrations which exemplify the favorable influence upon mind and body of an optimistic temperament, and I again quote from Lorand, who cites the case of the celebrated English painter, Mr. Frith, who died quite recently at the age of 92, and who when asked the reason for his vigor and robustness used to answer, "No worries and six cigars a day"; and the same author having found on the island of Capri an old boatswain of 80 years vigorously handling his oars, inquired of him the reason of his robustness and received as his answer, "Always merry." In the first case cited, I should not want to say that the six cigars a day were the essential factor in the longevity. I believe rather that it was the "no worries," but I recognize the contributing value of being able to gratify our little habits which cater to our contentment of mind.

So far, in discussing the importance of controlling the emotions, I may have conveyed the impression that I thought this matter was entirely within the individual's control. I don't believe that I should care to claim this, because I am somewhat of the opinion that it is at least partly a matter of temperament, that it, it appears to be natural, at least more easy, for certain people to be optimistic and have more control of their emotional faculties than others, but as the result of giving this matter more or less consideration in the past year or two, I am beginning to feel that it is possible for people at all ages to begin to acquire the faculty of such control. Nevertheless, like any other habit, if this is a habit, I am sure that the earlier one undertakes its accomplishment, the easier it is going to be later, and the more efficient and effective, and I am not so sure but what Dr. Barker of Baltimore is right when he claims that parents should begin very early in life to teach their children to control their emotions, to tolerate pain and to suppress as much as possible the tendency to that condition which is usually expressed under the term "nervousness"; and I think if these ideas could be carried out in the management of children in their early days, it would be much easier for the parents, and life would seem more stable and worth while to the individual who had been taught the importance of this matter, and I do not believe that the endeavor to create such im-

pressions in the minds of children need necessarily in any way mar their happiness or restrict their free development, or mitigate their childish pleasures.

Now when all the above has been said, we are still confronted with causes which depress the emotional state for which we are in no way to blame or are able to exercise little control. Among these may be mentioned, loss of near relatives by death, disappointments of love, failure to attain our ambitions, whether these be of a social or financial nature; but, fortunately, even here we can obtain some assistance by availing ourselves of that faculty of the mind, viz: forgetfulness, which is undoubtedly just as much a self-defense against diseases of the mind as are the antibodies and other natural physical protectors which tend to guard against the development of physical diseases, and though this faculty of forgetfulness might easily, and frequently is, used to our detriment, yet, when properly handled, it can be utilized as a protection during a period of readjustment. It is fortunate that the average man is so constituted that as time goes on he must naturally lose his sorrow. "Time heals all grief," and here also will power has its effects.

After all, is not this question of control of the emotions practically synonymous with exercising the will power, for, unless we have learned how and when to apply the brakes in the exercise of our emotional faculties, what is there to distinguish us from the lower order of animals except possibly the erect posture of our bodies and the greater craftiness which the human can display in the perverse use of his mental faculties?

#### NEED OF REGULAR SYSTEMATIC MENTAL AND PHYSICAL DIVERSION FROM OUR USUAL OCCUPATION.

The need and beneficial effects to be derived from systematic cessation of our regular occupation and the replacement of the latter by some form of relaxation, both mental and physical, seems to be as old as the history of man, and the antiquity of this record of man playing would seem to bear out the development of the theory that civilization with its manifold duties, its need of sustained mental and physical energy in order to make us capable of maintaining our individual parts in the complex life which the higher forms of civilization demand, was after all, a purely artificial thing, and certainly when one observes and reflects a bit upon the havoc which modern forms of living promote, and actually compel, one can hardly refrain from remarking that some of us at least are paying a very high price for our civilization. But here again we find compensation, for if in the evolution of the human, all his powers of offense and defense have been concentrated in the specialization of his brain, and this very specialization creates the ability to select his environment at will and at the same time to adapt himself as well as for his profit.

An enumeration of these diversions is, of course, not necessary at this time. Fortunately they are almost as manifold as is the number of individuals who need such diversion, and I shall content myself with hinting at a few of the more common and well-known methods by which people in all ages have been able to divert themselves and thus relieve the strain upon their mentality.

Foremost among these, both in importance and in the number of its adherents, is some form of outdoor life, and the increasing number of people who seek some form of outdoor relaxation is a striking commentary upon the artificial character of our usual methods of living. I have heard, for instance, golf called the great life-saver for people of sedentary occupations after they reach middle life, and though the writer is not intimately familiar with the methods of this game, yet he can see that if it is not carried to excess, the necessary amount of exercise in the outdoor air which it demands, taken together with the degree of skill which can be acquired in the practice of the play, and which must act as a mental stimulant if one is successful, will account for the large number of its adherents; and yet even here I suspect one must be on his guard for fear of overdoing the matter, and the recent testimony of the prominent New York business man regarding the detrimental effects of sustained golf-playing by both elderly and old people is suggestive. He says that in the last four years he has lost five friends of fifty or over who have died or were stricken with heart failure or paralysis while playing golf or immediately after it. All of them had taken up the game late in life, and with a view of improving their health, as well as for diversion. Although he cites the names of three well-known men who are over 75 and who seem to play the game with pleasure and profit, yet he concludes that when active elderly business men get ready to let up on their sustained work, they would be wise to let golf severely alone. Of course this is a single testimony and from a layman, and it should have little weight in the absence of scientific data. It is probable, however, that golf for the man long accustomed to a sedentary life of mental activity does make demands upon the heart and other muscles that may be excessive, and might prove dangerous unless he could restrain his activity and enthusiasm within very narrow limits at first.

Another very valuable outdoor diversion is the increasing interest in agriculture commonly known as farming. I use the term "very valuable" advisedly, because one who adopts this as his avocation has not only the pleasure to be derived from the outdoor work, but also that which comes from the knowledge that success brings a constructive contribution to humanity.

When one recalls the back-to-the-farm crusade of the past ten or fifteen years, and places himself in a position to interpret the meaning there-

of and also becomes cognizant of what has been accomplished, both by the example of men of wealth and through the medium of governmental and state education, one would find it difficult to overestimate the importance of this work from both a health and economic standpoint.

It is not surprising that modern agriculture makes a peculiarly enticing call to physicians, for its successful pursuit certainly brings into play a number of lines of thought and action with which we are familiar in our regular work, but it gives its relaxation because they are directed along different channels. The majority of physicians are scientists in greater or less degree, and though we often get far from the science of medicine in the practice of the art, yet many do this from necessity rather than from choice, and I think most of us recall with pleasure our laboratory experience while at college, and we know that every year the so-called science of medicine is increasing to the benefit of humanity. Therefore it is not surprising to find that hundreds of physicians have naturally and intentionally devoted their spare time and financial energy to one or more of the different lines of agriculture.

What more attractive laboratory can be found than a piece of land well suited for tillage, and what more enticing relaxation than to bring to this laboratory one's knowledge of geology, chemistry, biology, meteorology, and physiology; for certainly the agriculture of today is nothing more than a composite of all of these various sciences, and one has to reflect ever so little to realize the great variety of conditions of soil and climate, and the composition and origin of the cultivated soil, as well as the conformation of the surface and the great variety of plant growth which arises under these varying conditions.

One's knowledge of geology will inform him of the origin, formation and conformation of the land; his knowledge of chemistry will aid him in his interpretation of the elements that enter into the composition of soils; his botanical knowledge will be called upon when he comes to study the nature of the plants that make up his crop, and a study of meteorology will certainly assist in explaining the varied conditions of weather, which are such important influences entering into the success or failure of the agriculturist's life. Again, one's knowledge of anatomy and physiology is called into play in the breeding and rearing of livestock, and when one comes to study the low forms of plant life that cause diseases on the crops, a knowledge of biology is essential in our efforts to combat these enemies.

It would be difficult to say which of these various sciences is the most important, but certainly that of chemistry has contributed wonderfully in placing this occupation in the front rank of those different lines of work which contribute toward the support and well-being of

man, and this phase of the subject alone has attractive features enough to absorb one's interest, even though one never made any practical application of its principles; and it is safe to say that no other one thing has done more to change the character and arouse the interest of those who follow this calling, either for a living or for relaxation, than the simplifying and putting into every-day language these chemical investigations and conclusions.

Is it any wonder that farming today is calling for a higher type of workmen than almost any other occupation? It takes a large man to drive himself day in and day out, so to arrange his work that all of his time can be utilized to the very best advantage, and because of the climatic conditions, over which he has little control, he is obliged so to systematize the day's work as to utilize the rainy days to as good advantage as he does those when sunshine is abundant; and remember, because of his greater or less isolation, he is without the stimulation which comes from daily intimate contact with his fellows and which does much to keep us keyed up to the necessary pitch.

#### THE RELAXATION OF LITERATURE.

Of course there are a great many people who for one of many reasons could not be attracted for their relaxation to outdoor pursuits, and besides, in a climate like ours, such a course is impracticable for many months of the year; therefore I would like to take a few moments to outline what the reading of books outside our regular line of work may do for us along the lines of the particular hygiene which we are discussing.

It would take much more courage than I possess, as well as far greater knowledge, to do more than hint at what one might do along these lines, for in many ways there is no field of opportunity which is larger or more enticing, and which has more varied forms of attraction than has that of literature; and I believe if I were to be asked my opinion as to what was the greatest boon that had been conferred upon the human animal, I would say that it was the starting somewhere and somehow in the long-distant past of the power of the human mind to generate ideas, to express these intelligently and to be able to transmit them by the written or printed words for the use or pleasure of humanity, and I believe that these faculties alone would justify our existence.

It would be presumptuous for one of my limited knowledge to lay down any definite rules which it were safe to follow in order that other individuals might obtain mental relaxation, but it will do no harm if I mention a few titles of books which are representative of kinds of thought and action which have conferred pleasure, amusement and some profit.

Take, for example, the product of Shakespeare. Where can you find a person who has

produced a greater variety of material of such absorbing interest and, on the whole, more understandable to physicians, than has this man, whose three hundredth anniversary is being celebrated in all civilized countries this year. Like many other great men, Shakespeare did not attain full recognition during his life, but fortunately for the race, the appreciation of his work has been growing, and in spite of all the controversies which the growth of this recognition has developed, he is today, I believe, recognized as the leader in literature.

It would be interesting to develop the reasons for this high standing, but in view of the fact that so much has been said and written about Shakespeare and his works—more than has been written about most nations—I certainly won't attempt even an outline of it; but of these things I am sure, viz: he was able to take plots which had been used for similar purposes by writers of tragedies and comedies from the earliest recorded time up to those who were contemporaneous with him, and by his master mind, he was able to infuse into them new life, greater interest and permanent vitality because of his genius for true interpretation of human nature; and it is a striking fact that, with all the wealth of his material and great number of the personages which he characterizes, there is very little that is untrue in the representation of the thoughts and actions of individuals, not only of his own time, but also of human nature as we see it and know it today.

Take Hamlet, for instance. I think I have read it at least six times, the last time within a year, and I know I did so with greater understanding and more pleasure than at any previous perusal; and, whereas at first the principal character seemed to be nothing more than the prototype of thousands of individuals whose vacillating nature and indefinite purposes make them easy victims of every outward circumstance, I have since come to appreciate in the career of Hamlet a most interesting study in psychology. Although he and Macbeth depict similar types of monomania, yet to me Hamlet offers far more attractive features because of the likeableness of his personality and the refinements which he expresses until his mentality was undermined by his sudden knowledge of the fearful capabilities of the human animal in the attainment of its personal ambitions.

Again, as a study in the baneful effects to be derived from suggestion, where, for instance, can you find a better example than the effects of a thought as expressed in the Witch's Prophecy to Macbeth, which from that time onward changed the whole course of his career? And whereas, previous to this interview, to all intents and purposes he was one of the sanest of men, as evidenced by his accomplishments, the absorption of the idea thrown out by the witches was unquestionably the entering wedge which ultimately upset his whole mental balance.

Then, again, take the lesson to be derived from even a casual reading of *King Lear*. This picture of filial ingratitude on the part of the daughters, and the ignorance of human nature as exemplified in its ambitions on the part of the father, would seem to have been presented strongly enough to last the human race for centuries; and yet even today hardly a year passes but what our court records show controversies of a similar nature with the selfsame results, which indicate that this lesson which Shakespeare tried to convey has fallen for the most part on stony ground. Elderly people are today giving away their property without suitable safeguards, on the mere promise of an individual, relative or otherwise, to discharge a natural obligation without financial compensation, as long as care may be needed; yet almost invariably their initial enthusiasm is cooled in direct ratio to the amount of money or property which they have been able to get into their hands.

Now some might claim that, if they wanted mental relaxation, they certainly wouldn't go into the study of complex characters as depicted by Shakespeare, and if one feels this way about him, one still has access to his works in the form of his comedies which, for entertainment and pleasure, would be hard to replace; and one can easily forget the ordinary cares and harassments of a daily grind by skimming through either "As You Like It," or "Midsummer Night's Dream."

This subject of comedy, however, suggests the name of the other master who has characterized this phase of human nature, namely, Molière, who has often been called the French Shakespeare of comedy. To those of you who are not familiar with him, I would strongly urge the acquaintanceship to be derived from reading the comparatively recent biography by Brander Matthews, and then I am sure you will want to take up some of his well-known plays, and laugh as have thousands before you at the clean, faithful and humorous satire which he knew so well how to produce. We may think human nature has developed and made wondrous strides in the past century, but I doubt if one can get up from a study of Shakespeare or Molière without realizing that man's ambitions and accomplishments are, in the main, almost essentially the same now as they were in those times.

Although there are thousands of books which have been written for very little else than one's amusement, yet I wonder how many men after forty reread those produced by Mark Twain, which were familiar to them in their early boyhood days; and again, what better test as to how fast you are getting old can you make than by reading, for example, Judge Shute's books on "The Real Diary of a Real Boy," or his humorous characterization in "Farming It," which depicts the facility with which the native

Yankee can take the best from the new comer in exchange for that which has long outlived its usefulness. Another one of a similar nature is Booth Tarkington's "Penrod," who makes it simply impossible to fail to laugh and appreciate the perverse facility with which some boys can get into and keep saturated with trouble; and to those of you who are having difficulty in understanding the antics, idiosyncrasies and psychical perversions of the boy of seventeen, I would recommend the book, "Seventeen," by the same author. A study like this makes one realize what havoc sustained responsibility and anxiety produces in the adult, and renders him often incompetent properly to handle his progeny at this age.

Physicians, above all other workers, cannot escape being occasionally depressed by the results of ignorance and disease as they show themselves in the lower strata of society, and it would be difficult, if not impossible, to blind one's self to the spirit of unrest which is ebbing and flowing constantly around us. And though it may seem far fetched to recommend reading of this type as a means of relaxation, yet among the very large quantity of literature which has accumulated around this subject of social economies, there are a few books which are sane and comparatively free from bias.

It may surprise you to mention Ruskin as a social reformer, because those of us who know him at all associate his name with artistic things; and though much of his life was spent in constructive and analytical criticism of painting and allied subjects, yet his versatility permitted him to take up many apparently unrelated matters. Among these were his very advanced views on vocational training and social economies, and it is interesting to note that a majority of the present ideas which have been incorporated in industrial legislation, had their inception in the brain of this dreamer of over half a century ago. What these ideas were to Ruskin is shown in the effects on his mental and physical makeup, for then, as now, new ideas were combated and put into the melting-pot of adverse criticism before being accepted; but Ruskin's nature and temperament were unfitted for the storm that followed their presentation, and even a casual reader of his letters of this period can see the blighting effect of the opposition which his views engendered.

Like every other thing that Ruskin undertook, he entered into this subject of social betterment with enthusiasm and tremendous energy, but after a few years of practical contact with the people that he was trying to help, his keen mind apparently showed him the utter futility of his maintaining his personal effort, because of the incompatibility of his temperament as compared with that of those he was trying to help. I think this conclusion is a reasonable one after reading some of his letters written at this time, and I ask you to bear with me

while I take the liberty of quoting a portion of one of these letters. He said:

"It is not so much from failure of my interest in this class that I have ceased from personal attendance, but I ascertained beyond question that the faculty, which my own method of teaching chiefly regarded, was necessarily absent in men trained in mechanical toil, that my words and thoughts respecting beautiful things were unintelligible when the eye had been accustomed to the frightfulness of modern city life."

And I also quote the following from an appreciation by one of his ardent admirers, and I doubt not it will be understandable to those of you who, though interested in social betterment and rebelling against the apparent injustice of many of our methods of living, yet realize that it takes one type of mind to initiate theories of reform; it takes a totally different and practical type to take such theories and mold them to existing conditions. The quotation is:

"In his earlier writings and lectures, one can see that he thought that the spirit which loved and admired and welcomed beauty and drank at its springs was there in humanity; but as the years went on, he began to see that it was not so. He saw that all the world over the majority of the human race had no care or love for these things at all. He had believed that all human beings were dull only because they admired or tried to admire the wrong things, and he thought that they had only to be shown the right things to admire and love them; but he found that people were at heart indifferent and worse than indifferent, that the world was full of ugly desires or low delights; that men were selfish and cruel and unjust; that they loved wealth and comfort and display; that many people lived from childhood to age under the shadow of base influences and devastating thoughts; and so he began to see that if they were to admire and love what was pure and noble it was not enough only to point out the work, but that the nature of man must be somehow purged and changed."

Now, lest one should feel that in heartily agreeing with the sentiments just quoted, they felt it would be useless to try to do anything for this class, let me just mention the titles of two books, the authors of which have been living examples of the ability, through personal contact, to infuse into people, in the so-called lower strata of society, ideas which, through practical application, inevitably raised their standards of living and improved their methods of thought. Miss Lillian Wald, in her series of articles which recently passed through the *Atlantic Monthly*, depicting her work in the Henry Street Mission in New York City, and Miss Jane Addams' work entitled "Twenty Years at Hull House," in Chicago, are certainly far more interesting than many novels of today. By their sustained activity, almost superhuman tact and judgment, they have brought into practical application most of the theories and ideas first presented by Ruskin.

#### THE INFLUENCE OF FRIENDSHIP.

One other mental diversion which I would like to mention before leaving this subject is friendship.

Did it ever occur to you what a scarce article true friendship is, and where can you find a body of workers who need friendship more, or as a rule have less of it, than physicians?

One who reads much is struck with the amount and quality of the friendships of such personages as Gray, Charles Lamb, Carlyle, Mrs. Browning, Ruskin, Dickens, Emerson and many others whom you will recall, and this is not surprising, for their time and talent tended to promote and develop this virtue; but why is it in all our work we find so little that is really true and stimulating in the contact with our fellow men?

Someone remarked to me not long ago that the present day was more devoid of true friendship than ever before, which he ascribed to the intensity of our life and the greed for transient things. I had just been reading some of Plutarch's Lives, among them his Julius Caesar, and later had read the biography of several successful physicians of the eighteenth century, and the thing that impressed me most forcibly among the many interesting details was the devious trail of envy, hatred and malice which followed in the wake of their success, and I was pessimistic enough to conclude that human nature was much then as now.

I am not now speaking of the so-called Platonic friendship between men and women. History is full of the failures of this type, and he who plays it does so at his peril, but what I have reference to is the possibilities to be derived from true friendship between man and man. Someone has said that "a faithful friend is the medicine of life, for what cannot be effected by means of a true friend, or what utility or what security does he not afford? What pleasures has friendship, and the mere beholding of him diffuses unspeakable joy, and at the bare memory of him the mind is elevated!"

What would it not be worth to us as physicians to be in contact with fellow workers in whom we had absolute confidence, whose company we sought through those occasional periods of depression which come to all active mental workers, and with whom we could exchange confidences with security, and to whom we could give of our best in return?

Fortunately there are occasional isolated instances in almost every community which show the possibilities in this direction. The writer knows of such between two most successful business men who found time to get in contact frequently, notwithstanding the hurried and incessant calls of a busy life. These men held different views on political and religious matters, but subjects they seldom discussed, but on other topics they exchanged confidences, and assisted each other in their work.

ciation with the other one of the largest elements of his pleasures in life, and this intercourse was maintained with absolutely no lessening of their domestic obligations.

Unfortunately, such an experience is sought for and found by only a very few of us, and if it does occur, it is apt to be late in life.

It is useless to ask why this is so, for life is so complex and the speed of living is so intense that apparently we have little time or inclination for anything but the absolutely necessary things of our existence.

Many of us professional men leave college with a smattering of the so-called essentials of our foundation knowledge which we too often mistake for a superstructure. We enter the struggle for existence often handicapped financially. We are soon struggling for what we think belongs to us, and we fight and are fought. We inevitably tread on our confrère's toes, we hear the plaudits of our patients, and have nightmares engendered by false visions of our competitor. If we are not on guard we become inflated with so-called up-to-dateness of recent medical education, pitting it against the years of solid practical experience which come to the older practitioner, often to our great personal disadvantage and our patient's loss. We acquire the pessimistic habit in our prognoses, due often to lack of preliminary training and temporary loss of our common sense and the sane perspective which only years of actual responsible contact with diseased humanity can give. The readiness with which we are called upon to treat what seem like dangerous conditions, and the ease with which a pneumonic consolidation, for example, clears up under our skillful attention, and the use of a recently exploited drug, rival the tales of miraculous cures of medieval times; or we may witness an operation by a man of experience and skill, and forthwith the siren call of the knife—or is it the jingle of another metal—hypnotizes us before the ability for differential diagnosis can be acquired as the result of study and mature judgment, and we find ourselves in the dangerous whirlpool of surgical practice.

If we are specialists then, for example, every cross-eyed child should first have a tenotomy, every case of difficult nasal respiration or a slight impairment of hearing should have the projecting spurs of the septum, or even most of the latter, removed by a sub-mucous; and, of course, tonsil and adenoid tissue in the place where nature intended it should be is dangerous, regardless of the fact that patients have acute ears without adenoids, and go through life pretty comfortably with most marked nasal deformities; and the just as important fact that a chronic otitis media with thickening goes on its progressive course downward after a free current of air has been allowed to enter the pharynx by surgical procedure.

If we are general surgeons in embryo, then a

pain in the abdomen convicts its owner of concealing something dangerous to life, and we all know what an abscess in the appendix can do, and we also know that it is easier and safer to enter the abdomen of the other fellow than it is to take any chances with nature or expectant treatment.

Now don't mistake me. I am not condemning surgery, its utility or life-saving field. Every procedure in the few that I have mentioned has its legitimate opportunity, and there is just as much danger in cowardice as there is in unnecessary aggression, and the physician of years of experience who is doing what he can to keep abreast of the times is only too willing to admit this fact.

But let us get back to the picture. Now what is nature and environment doing to us as individuals all this time, because inevitably we are being molded, and we cannot escape the unvarying law of progress? Incidentally to the practice of our profession, we may have taken on domestic and other responsibilities; perhaps we express our civic interest by political ambitions, or we would like to piece out our meagre incomes, and we make some financial ventures. Anyhow, we become absorbed in the struggle for existence.

At first, as a result of our college momentum, we keep up the study of our art, and even purchase some current text-books or take one or more medical journals and attend local society meetings, and perhaps the state or national gatherings, but almost imperceptibly inertia creeps over us. The physical drain from long rides and night work brings us to our patients foggy mentally and possibly nervous physically; and as for reading medical or other literature or the writing of history records, why they are physically impossible! Soon all cases seem to look alike, and we often get so that if we recall with certainty the location of a certain medicine in our drug closet or its formula in our mind, for purposes of transferring it to paper as a prescription, we congratulate ourselves. By and by, medical journals accumulate without even the wrappers being removed. We receive notices of regular meetings of the medical societies, but we often fail to attend, or if we do, we are reluctant to contribute. We occasionally read the notice of a musical production, or the title of an enticing play, or the name of an attractive, stimulating speaker, but the vision to attend is only momentary, and we go on our accustomed way.

Then something suddenly happens: perhaps we have a birthday and we realize that we have entered upon our fourth or fifth decade, or we have been wrestling with a serious illness and been obliged to call for help, or, in the course of a day's work a valuable life slips through our hands and we awake to the fact that we have been practicing medicine ten, fifteen, twenty years. If the jolt is severe enough and we have

any latent resistance, we come to, take an inventory of our surroundings, and perhaps are humiliated to find that, instead of doing constructive work in the practice of one of the most beneficial of occupations, we have just been working for a living, but in doing so we have forgotten the value of maintaining an intimacy with our fellow workers, have failed to realize the fickleness of public approval, have allowed the biased opinion of a disgruntled patient to have too great valuation, and thereby caused antagonism in a fellow practitioner. Perhaps in the course of our career we took up an avocation, ostensibly to relieve the mental strain, and we have unconsciously made of it our vocation, to the detriment of our professional practice.

If we have become pessimistic we shall rebel at our condition, we shall blame the fickle public and unscrupulous competition. Perhaps we try to excuse our state on the ground that we settled in a rural community and lack the stimulating influences of contact of many individuals, in fact, we may bring into being dozens of excuses, and utterly fail to grasp the fact that we are what we are very largely through our own lack, and principally through failure to recognize the inevitable fact that permanent, steady, substantial growth comes to the human just as it does to an occupant of the vegetable kingdom: through constant absorption of those elements of growth which are placed about us in such abundance, but which must be separated from chaff and useless material by steady, up-hill, sustained, hard physical and mental labor.

If we are game, and there is still time and ambition, we shall reconstruct our thoughts, avail ourselves of what there is of our mental capital, and place ourselves in a position to receive stimulation by contact with others, and by study to practice medicine for the love of the work. If, on the other hand, our awakening has been only momentary, and we become discouraged by the apparently unequal contest, then we shall settle down and allow the moss to go on with its growth.

Occasionally we see examples in communities which are exceptions to the picture which has just been painted. Men, through force of sustained work, actual mental ability, or through the power which comes from physical traits, forge ahead and become apparently successful, if this success is measured by the large volume of their work and the financial return which this brings to them; but at the risk of being considered utterly pessimistic, I would just like to mention that success, if measured by excessive work, has also its drawbacks, and I believe that these cases more than any other need to exercise the greatest care and supervision of their lives, else they become mere automata and go through the daily grind with such intensity that the practice of medicine or surgery becomes little more than the taking in of its financial remuneration. The community needs these men,

and because of this they should so order their lives that they will be constantly fit to discharge their obligation to their constituents; but how can they do this if practically every minute of their waking hours is taken up with consultation, operations, or the getting about from place to place? Perhaps I am mistaken in my belief that these men, more than any others, need to have regular hours for relaxation, a certain period each day for study that they may become informed as to what the other fellows in their line of work are doing, and the periodical personal observation of other men's work that they may profit as only one can who sees ocular demonstrations.

I have known men of this type practicing in a semi-rural community, who rather boasted of a day's work consisting of from two to four major operations, fifteen house calls, and over twenty office consultations, and I know that they were approximately correct in their figures. It is possible that each case got its full value, and that the physician and surgeon was satisfied with his results, and that such sustained labor is consistent with a well rounded life that meets one's ambitions.

On the other hand, I know of men of the same type who are trying to limit the volume of their work in recognition of the need of some sort of relaxation, but because of the steady habitual grind of years, they do not know how to go at it, and the fear of financial loss incident to new moves is just as real in medicine as it is in commercial life; but while they have been floundering around and just thinking and not acting, the years are going by with express-like rapidity, and many of these men show the effects of age and lack of diversion by a little less clearness in their thinking, a tendency to change an arrived-at conclusion, and a hesitant character in their previous manual dexterity. They begin to give up that elasticity and flexibility of mind which are so essential if one continues progressive, and finally they take on a puttering habit in their work, a characteristic which is usually unconscious to its owner, but all too readily observed by the discerning laity, and puts on the stretch the loyalty of the latter.

In conclusion, I desire to emphasize the point that I recognize, that there are many other ways and means of developing mental optimism and obtaining relaxation of mind and body, but this attempt at an outline has already grown beyond the original intention and, besides, I doubt not I have advanced enough ridiculous ideas to meet the usual fate of one who says unusual things in an unusual place, and you may feel like advising the writer to take his own medicine, in so far as it relates to the control of the emotions.

It may be that the needs suggested are magnified and the pictures described overdrawn but in either case I have had the pleasure of the diversion from consideration of one's usual thoughts and responsibilities in connection with the practice of medicine.

### MENTAL PREPAREDNESS.\*

By JAMES J. PUTNAM, M.D., BOSTON.

THE nations of Europe are engaged in an unexampled conflict, for which the name "calamity" seems too trivial, the issues are so momentous and the emotions involved so varied and so intense. We are warned that a similar upheaval may sometime reach our shores and are urged to prepare ourselves to meet new military and civic dangers.

But when one thinks seriously on preparedness in this sense, the problem begins to widen and to become more personal, until the question of the war in Europe—its causes, its emotional history, its probable results, the obligations of America with reference to international affairs—relates itself very naturally to the problem with which these lectures aim to deal: What shall we do to make our children and ourselves mentally more stable?

But no sooner is this question thought upon with care than it is seen to merge itself in the still larger one: To what end should one seek mental stability? Have we the right to wish and work for such benefits as health except as an indication of right thinking and acting in the past, and as a means to better thinking and acting in the future? The power to reason clearly and without undue emotion might indeed be welcomed, very properly, as an inheritance, and as a sign of right living in a physical sense; but when present in its best form it necessarily implies a conscious devotion to suitable aims, and the subordination of narrow and private interests to the interests of the community. The exclusive pursuit of private pleasures becomes intolerable as a principle of conduct and is even recognized as accounting for a large share of the evil in the world, or, more strictly, as indicating that the individuals whom it characterizes are still relatively uncivilized or immature at heart.

I call attention to the following propositions as especially significant in this connection:

1. The obligations above referred to seem at first to have reference to one's duties toward particular persons or groups of persons, or to particular situations or institutions,—the members of one's family, one's friends, one's city, state or country, and so on. But presently it is seen that underlying and including these special obligations, a widening series of ideal obligations may be traced—as, to justice, loyalty, humanity, and disinterested love.

2. Another very important principle is that men who wish to make the best of themselves

should not be content merely to work toward good ideals. They should also learn to see, in detail, what the influences are within themselves that hinder the attainment of the ends they seek. Even the pursuit of ideals of a good sort is very often colored and modified by egoistic tendencies. And although the recognition of the fact that this is so ought not to make men reject altogether, as unworthy, their efforts in good causes, still, a due respect for themselves ought to make them feel obliged to trace out the influence of these subtle enemies.

3. Neither of the above mentioned principles can be made available in practice except at the cost of labor and through the acquirement of skill. It must have been borne in, more and more strongly, upon every thinking man, through observation of the present war, that satisfactory results, in whatever direction they may be sought, are to be brought about only through persistent and coördinated effort, whether it be in the selection of a general policy, the recognition of our obligations as citizens of the world, or the acknowledgment of our more immediate obligations as members of the family, the state, the church, or whatever other social ties each person feels as binding. No one is likely to succeed in making practical the beliefs which he comes to hold without bestowing on the task a large amount of faithful and consistent work.

With reference to the first of the three propositions, it may be admitted that some proof is needed before men can be called upon to agree that they owe these assumed obligations to the community;—or, indeed, that they are under any essential obligation to lead an ethical and moral life at all, or to acknowledge religious ties in the ordinary sense. It is true that the claim for the existence of these bonds is not often called absolutely in question; but some people often think so lightly of them that they fail to gain from them any strong motive for their guidance, while others profess an allegiance which really lacks genuineness, and so place themselves in a false position.

In fact, every man should be thought of as being at once a member and a representative of communities and social groups. No man can stand alone,—not only because he cannot practically exist by himself, and never does exist by himself, but because he is so constituted that, from the very nature of his mind, he cannot be conceived of as isolated and single. If societies did not actually exist they would be ideally constructed. Men do not form societies solely because they are forced to unite for protection or convenience, however this may seem to be the case. The philosophic teaching on this subject is very definite and impressive. It has been made clear that the more fully a person tries

\* Read before the Conference of the Massachusetts Society for Mental Hygiene, Ford Hall, Boston, Nov. 19, 1915.

to give expression to his whole self, the more fully he finds himself living outside of himself.

The principle that no man can express more than a fraction of his meaning if he strives to live for himself alone; that individualism is mischievous if it does not lead to an ever expanding collectivism, personal and ideal; that men are in the world, not for what they can get (for themselves alone) but rather for what they can give:—this principle should be the pillar of cloud by day and the pillar of flame by night to all men seeking to prepare themselves for the battles of life. There are illustrations in plenty to show how frequently it has formed a theme in the writings of men of philosophic insight. The "Seven Sins of Dante" have relation to the attempt on the part of individuals to set up their individual passions and desires in opposition to the best interests of the community, in a narrower or a wider sense. The result always is that the community throws back such a-social or anti-social forms of expression upon the author, and this constitutes his punishment. Even those who seem most inclined to throw off their social ties,—as the misanthropes, the shy, the self-conscious, the self-ostracizing persons, and, strangely enough, persons whose conduct marks them as effectively anti-social—are found, when scrutinized, to be peculiarly dependent, in spirit, on the affection and approval of their fellow men. The tragedy arises from their inability to express or accept this affection in an advantageous form.<sup>1</sup>

It may be true that, in a practical way, we cannot devote ourselves to the welfare of humanity at large. But we can devote ourselves to the more obvious tasks at which I have hinted, in the spirit of a larger humanity. We can endeavor to act as if living in a world in which the influences are recognized as binding which we theoretically admire as best. And we can try to detect in ourselves indications that our efforts are otherwise than genuine and can seek, without undue emotion, to see what private interests we are really serving and what correction needs to be applied. I realize keenly the difficulties in the way of doing this and shall refer presently to their nature. But I am convinced that it is a great deal to see clearly what the path is that one desires to follow; and I have been much impressed to observe how many persons fail to get what I consider a proper background for their conduct.

One hears it said, right and left, that marriages are unhappy. But with whom does the fault lie? With what preparation and realization of its obligations is the marriage state entered on? Surely it is not held sufficiently in view that immense sacrifices must be made not only by the husband for the wife and the wife

for the husband, but in the interests of one's belief in the principle of union here involved.

Then, what preparation of a definite sort is made for citizenship? Here and there, no doubt, a good deal. It is, however, one of the failings of democracy that under this form of government men have not as yet found means to secure a sufficient amount of cooperative devotion on the part of its citizens to make the nation, as a unit, successful in its tasks. We blame certain nations because in their effort to give their own states a successful policy, they fail to recognize their responsibilities toward other nations; fail, in short, to recognize sufficiently the principle of the ideal background of cooperative life to which I have alluded. One might think that the individual citizen could properly be appealed to for support of this principle. The appeal would be in vain, however, unless he had made it a rule of conduct in his own life. Meanwhile, the example set by certain races who have kept alive their national spirit and have spread abroad their national influence, yet have not maintained themselves as a community in a political or military sense, should not be forgotten. Whether the example of these races is to be literally followed, or not, the fact referred to may be taken as a new chance for upholding the declaration that it is not enough for an individual, a specific group of individuals, or a nation to take its own success as a sufficient criterion for the justice of its course. To work for one's nation seems a virtue; but whether or not it is virtue depends on whether the national success is thought of as a final goal. If it is so thought of, then the sacrifices made by the individual to secure it become the expression of a peculiarly subtle and pernicious form of selfishness, a tendency anti-social in spirit though social in form.

Akin, in principle, to this danger is another which is everywhere to be seen. Many people have, namely, a strong feeling that they should only recognize attachments that are personal in character; or, at any rate, they are disinclined to admit that they owe a still greater loyalty to ties which are not personal. The very warmth of these personal attachments induces in such men the belief that it would involve a painful sacrifice of something which they do and should hold very dear if they were asked to recognize that the love for a single person could under any circumstances merge itself in love of the idea for which such a person stands. Yet every one admits that when private and public obligations conflict, the latter must often supersede the former:—

"I could not love, thee dear, so much  
Lest I should love thee less."

And indeed it should be seen that through the very fact of this sacrifice the personal relationship may gain in strength and value, instead of losing.

<sup>1</sup> Rev. Edward Everett Hale's "Man Without a Country" may be remembered in this connection, in which the change of sentiment is pictured in the mind of an exile who believed himself wronged to desert and curse his native land, but found at last that his love of country was his strongest passion.

Although the principle according to which a man stands in intimate and necessary relations to the community, or to the idea which the community represents, seems so obvious that when studied in general terms no one is inclined to contradict it, yet in practice it is constantly contradicted. Some persons are unwilling, others seem unable, to acknowledge their social bonds; and although the contrary motives are usually of a selfish sort, yet, strangely enough, it often happens that the very strength of the inward craving for the affection of one's fellow men leads to an instinctive reaction against its expression. Thence come the habits of shyness and self-consciousness which may cause a person so affected to be accused, and to accuse himself, of offishness and a preference for isolation. The mental tendencies and temperaments of such a person need to be made the subject of close study. The main question is whether the desire to withdraw oneself from society is prompted by the wish to grasp an opportunity to serve society in some better form, or by a secret sense that one's affections are misplaced; or a dread lest they may fail of recognition and so lead to discomfiture.

Then, too, the true functions of what is called "independence" and "individualism" are liable to be misapprehended. The question is, again, whether the kind of independence and individualism that is actually cultivated tends to an intensification of egoistic introversion, or, on the contrary, to a new and better movement of a social sort. These qualities are of real value when they are used in the interests of a higher morality. One must not be either too dependent on the good will or affection of one's neighbors, one's friends, or even of those toward whom one stands in relations of the nearest and most sacred sorts. In fact, it is just here, with reference, for example, to the relationship—oftentimes so tyrannical and stifling—of parents and children, that independence needs preëminently to be preached. One can hardly go too far, however, in acknowledging one's dependence on such principles as those of justice and loyalty and disinterested love, and even—if one does it with open eyes—on the persons whose attitude and affection represent these principles; and the deep and mutual love of the mother for the child, in so far as it leads both to a wider sympathy with their fellow men, is a feeling that is precious. In short, while independence of others is often emphasized as a means of intensifying one's sense of power and gratifying one's egoistic propensities, thus becoming a social influence, there are two reasons of a practical sort which do in a measure justify the striving for the possession of this quality. These are, namely, because independence is useful as a protest against the tyranny of social conventions that have become too narrow, and because it is capable of serving as a protection against personal relationships that

threaten to become too overwhelming or too close.

If, now, it is as evident as I have made it appear that men ought to live so that their lives will be representative of the spirit of the community at its best, why is it that this aim is not more often and more strongly cultivated?

It is certain that men are pulled strongly, and by influences of which they are but imperfectly aware, in various directions adverse to this goal. Numerous attempts have been made, in figurative and literary form, usually in the interest of ethics and morals, to give expression to the influences here at stake. Bunyan's "Pilgrim's Progress" is a typical example of these efforts. It is, however, only within a relatively few years that it has been seen that the attempt to classify, and thus in some degree explain, men's tendencies toward selfish, anti-social conduct must, in order to be successful, be based upon medical psychology. For the difference between sickness and health is a difference of degree alone, and the tendencies which are exhibited in what one calls "diseases" of a certain sort, and can best be studied therein, give inestimably important clues to a knowledge of behavior among persons who count themselves as "well." The "symptoms" of many nervous disorders—those, namely, in which the emotions are primarily involved—are, for some purposes, better definable as "modes of reaction" in the face of situations of difficulty. When looked at from this standpoint they are seen to be the equivalents of kinds of "behavior," such as are usually looked upon as more or less admissible or more or less objectionable,—and, in either case, as compatible with what is commonly defined as "health," although in fact they are not compatible with the best sort of health.

To look upon behavior in this way brings us back to the contention of the earlier pages of this paper, where it was claimed that the value of a man's mental health is to be estimated in part through considering how it is to be employed.

The nobler qualities that the war has brought to light are qualities of a highly social order. The baser qualities are those of undeveloped, relatively immature, a-social, pleasure-seeking, and often cruel beings,—beings capable of generosity and devotion of a certain sort, but not of a sustained disinterestedness of a high order, or of a devotion such as sees in its object (the person or the clan) the embodiment of an idea and an ideal. The consideration of these baser qualities and their history—on some points of which I have already touched—constitutes the study of the second of the three main propositions defined on an earlier page.

The results won by civilization are often far less thorough-going than those observers might suppose who judge the members of society only by their professions and their ordinary behav-

ior. It is easy enough for men to conform to manners and customs of a kind of culture to which their inmost feelings—or, to speak more accurately, a part of these feelings—fail to correspond. Men may easily dress alike, use the same language and forms of speech, join their neighbors in social groups which have a high standing and reputation; and yet they may carry with them—partly or wholly buried in their minds—characteristics that belong to a culture of a far more primitive sort than that which they assume themselves to represent. The two sorts of tendencies thus represented are often so widely different, even so antipodal with reference to one another, that many persons—and indeed, in some measure, all persons—may, in a sense, be said to lead double or multiple existences; and the question is, in accordance with what laws or principles can one best describe the situation that obtains?

The principles that seem to me chiefly significant are the following: In the first place, the human race, as a whole, undoubtedly does move toward a type which we can represent to ourselves ideally, though only ideally. This is the goal of ideal perfection, as above alluded to. The evidence is too strong to be called in question that an influence is actually at work in the world that indicates the existence of such a goal and points the way toward it.

But this influence, although unconquerable and indestructible, exerts but a slight amount of force from moment to moment, and may readily be pushed aside. Every man, and still more every child, is under a constant temptation to take, instinctively, the course that is easiest and most natural, and then to seek to justify himself for doing so. He may, indeed, do this consciously within certain limits; but the unconscious yielding is the more significant than the conscious. Thus, we are led to revert to simpler states, in which less is demanded in the way of self-sacrifice and more is granted in the way of self-indulgence. In short, men tend to maintain within themselves, as affording opportunities for relief from toil and for actual self-indulgence, habits of thought and feeling of objectionable sorts. The child in us lives forever, intermingled with our adult tendencies, and while this is in some respects fortunate (since childhood is in some degree the golden time of life), yet it is also unfortunate. For childhood contains elements such as the self-respecting and self-knowing adult cannot tolerate, unless, indeed, after they have been transmuted and assimilated, so as to form suitable ingredients of a broader and a better life.

How shall men learn to deal to the best advantage with this tendency to reversion, and how shall they best help their children to neutralize the temptation to indulge in it?

It is often felt, and has often been said, that the growing child, the adolescent, and eventu-

ally the adult, must learn to "repress" what are denominated as his "evil passions." To say this is to state what is but a half truth; and furthermore, it is to indicate an educational effort which is in many ways pernicious. Some primitive, elemental tendencies must, it is true, be put down with a strong hand, in so far as there is no better way. But it should never be forgotten that the forces represented in these elemental tendencies—the source of so much over-intense and even fierce craving—cannot be suppressed to the extent of annihilation and should be made use of, so far as practicable, as stepping-stones toward a richer and more spiritual life. Any one who strives to repress these tendencies, without giving them the chance to convert themselves into something better, may merely be shutting up, as if in the box of Pandora, the germs of future mischief.

To some extent, indeed, a relative repression may and must go on, and men's æsthetic future, their poetry and art, will be the richer for it and serve as an outlet which is often entirely legitimate; for we cannot turn all our feelings into knowledge and wisdom of such a sort that they can be expressed in words. But if the elemental passions are too insistent, or if the repression of them is over-done or too high handed, then these stifled tendencies will seek redress, and may obtain it through inducing what may be called "symptoms," or, again, through setting up unfortunate traits of character (more unfortunate, perhaps, in reality than in outward show) which form a sort of compromise between the elemental tendencies of immature type and the strivings inspired by conscience and the pressure of society. Persons so afflicted—and the statement applies in some degree to all men—cannot feel themselves either wholly free, wholly at home with others or themselves, or as if living in a wholly real world.

How shall the education of the child be arranged so that he may avoid, at least, the worst sorts of these mischances? I can indicate only in barest outline a few of the principles at stake.

In the first place, it should be realized that the same forces are immanent and vital in the child that have brought mankind to where it is and that will carry it still farther. Theoretically,—if everything could be arranged as in practice it can never be,—a real opportunity of usefulness and happiness, a real function as member and representative of the community, is conceivably before every child. This principle the parent and the educator should always bear in mind, striving to see, for the still ignorant and mystified child, what the future might have in store for him provided he should show his best power.

Next, the parent and educator should have in mind, when dealing with the child, the long

forgotten history of their own early and earliest childhood,—partly wayward, as it doubtless was, and at all events widely different from what their present outward thoughts, acts, and feelings would suggest. The material for this degree of self-knowledge is, thus far, in the hands of a relatively small number of persons; but it is available to every one who will give sufficient time and labor to the task of seeking it. In the absence of the requisite self-knowledge on the parent's part, the next best course is to abstain, so far as possible, from interference with nature's processes, avoiding the attempt to force the child too hastily into the mould of adult customs, but studying, meantime, his meaning, and giving him a truly humble sympathy.

If, in pursuance of his best destiny, the child could move steadily toward some even fairly adequate goal of social companionship and usefulness, all would go well enough with him. But at each moment, and especially at the various critical moments of his history, he must meet obstacles, to be surmounted perhaps only with effort and assistance. If the obstacle is too great, the tendency will be strong to shirk it; and this tendency, at first negative in appearance, becomes at once more and more strongly positive in proportion as the temptation to follow the broader path of pleasure or indulgence develops its powers of attraction.

Every child is permitted to be an egoist,—partly, perhaps, because it is instinctively felt that in this world of strife a considerable amount of self-assertive tendency counts as an asset of value. But unfortunately, with many persons, to be once an egoist is to be always an egoist; and from childhood on the game may be played—not indeed, with the whole of one's complex personality, but with a part of it—of finding ways to be egoistic and self-centered without seeming to be so.<sup>2</sup> Vanity and egoistic self-indulgence may cloak themselves under the disguises of overdone humility, sorrow, depression, pride, world weariness and endless other forms,—even that of self-destruction, which usually means withdrawal from the world of effort, carried to its final term.

The point of next importance in the child's development is that at which he begins to seek an outlet for his—altogether natural—passion of love, in the form of love for some other person to whom he may attach himself. The dangers here are manifold, and are rendered doubly subtle through the fact that another person's personality is involved. The attitude of the child, under these conditions, is best guessed at by reflection as to the attitude of the parent. Is this always—in the case of the mother, for example—one of disinterestedness alone? Or is it in part her own feelings of self-indulgence that the mother loves to foster in her dealings

with the child? How is it about the only or the preferred child? Truly, the lot of such a child is liable to be a hard one.

Finally, and to conclude, I wish to say a word about the imagination of the child, its legitimate uses and the dangers of its abuse.

His glorious power of imagination is one of the child's best attributes. Through it he can learn to see a world that seems more real than the world of things around him, to live in which seems to live in possession of all that one desires. But those who have seen at close range the results, in later years, of the indulgence, on the child's part, in an unbridled substitution of this imaginative riot for the toilsome world of real life (which greatly needs to be illuminated by imagination of a better sort) will have learned that this tendency has another side. Everything that happens to the child should be a bridge leading to a broader life. If his experiences do not have this end; if his pleasures are taken too much in and for themselves and become sources of self-indulgence; if the child, fascinated by the creations of his fancy, forgets that he must keep himself their master, his pleasures and his fancies are liable to turn upon him to his harm.

Both the prevention and the cure of these evils are best brought about through a thorough-going attempt to find the truth.

---

## THE MEANING OF THE MENTAL HYGIENE MOVEMENT.\*

By WILLIAM A. WHITE, M.D.,

*Superintendent, Government Hospital for the Insane, Washington, D. C.*

I SEE in the audience a number of gentlemen who are connected with institutions for the insane in Massachusetts, and I believe there are a number of social workers here. I am not going to speak to them, because I believe there are a great many persons who have been attracted to this meeting from advertisements that they have seen or notices in the newspapers. This is a new movement, and I believe that those are the people we want to address; those are the people whose interest we want to stir up in this movement, and so I shall talk to what I believe to be a more or less mixed audience, and I shall try to tell them, in as simple a way as I can, what I conceive to be the meaning of this mental hygiene movement.

Now I have no doubt that perhaps one of the first questions that comes to your mind in connection with the mental hygiene movement is, what relation it has, if any, to insanity? and perhaps, after all, what insanity is? and I will

\* Cf. Meredith's novel, "The Egoist."

\* Read before the Conference of the Massachusetts Society for Mental Hygiene, Ford Hall, Boston, Nov. 17, 1915.

try to answer that question for you to begin with. Insanity is a word that has been used for a great many hundreds of years, and a great many different people have tried to define it, and they have usually failed, but I think I can give you some idea of what the word means and what class of people it refers to.

If you will think of a primitive community out in the Middle West during the times when the Middle West was yet the frontier, you will realize that a member of that relatively primitive community could, if you will think of Mark Twain's descriptions, ride down the centre of the street and yell and holler and shoot, and it was thought to be a comparatively normal kind of conduct and nobody thought it was strange and nobody interfered with it. Now when communities get to be older and more civilized, when they get to be more congested, one can't do anything that he may happen to choose, without crossing the path of someone else. Then certain conventions of conduct have to be followed and there have to be greatly restricted lines of conduct, so that if a man acted as I have described, he knows just where he would land in the city of Boston. It might be and probably would be, in the jail. In other words, he is exhibiting a certain type of conduct which the community—to speak in slang phrase—won't stand for, and they simply remove him from it.

In the group of people that are called insane, are people who exhibit a certain type of conduct which cannot be tolerated in the community in which they happen to live. I remember not long ago, in walking down to my quarters at the hospital, a woman threw up the window, thrust her head out and shouted, "Murder!" Nobody paid any attention whatever to her. We were used to that sort of thing. She shut the window down, and went back to bed. She was in a community where she was understood. But she could not do that sort of thing anywhere outside of an institution without being shut up for insanity. And so it is that any individual must conform to the established forces of the society in which he lives.

Now what is the characteristic of these types of conduct of which I have been speaking? It is social inefficiency. The individual who manifests a kind of conduct that is calculated to tear down the existing conventions, to deviate greatly from the normal conduct of the community,—that person is an individual who has to be relegated to some place other than a position of free citizenship. Thus a certain type of social inefficient conduct may be said to be insane conduct, and so the word insanity comes to be, as I see it, not a medical term at all, but a social term which defines a certain kind of socially inefficient conduct.

Now let me elaborate a little further what I mean by conduct. You or I or anyone else can think all we want to about threatening some-

one's life; we can formulate all sorts of plans about meeting him and shooting him, as long as we don't say anything about it and don't do anything about it. But let us for a moment start to put such a plan into execution, and that moment something will happen to us. In other words, we may have any sort of desire, our thinking apparatus may function in any one of a great number of ways, but so long as it doesn't manifest itself in our outward conduct in any way, society hasn't any interest in it. So then, I would say that insanity is a certain type of socially inefficient conduct, a certain degree of socially inefficient conduct that causes trouble in the community.

Now there are a great many different kinds of socially inefficient conduct. The insane are one type, the feeble-minded are another type, the criminal are another type, the neurotic and nervous patients are another type, and I call your attention to the fact that in the exhibit downstairs, if you will go over the various charts of admissions to different institutions and hospitals over the State of Massachusetts and the penal institutions and asylums, you will see that all these different individuals are characterized as juvenile delinquent, alcoholic, syphilitic, etc.; you will see that all these different varieties of people are recognized in that exhibit as coming within the purview, in one way or another, of the general movement that this meeting represents,—the mental hygiene movement.

Now let me give you some illustrations—the type of socially inefficient conduct of the feeble-minded. The feeble-minded individual is an individual who has not developed to the full mental stature of maturity. We speak of the feeble-minded as having a certain psychological age. We mean by that that they have reached a certain age mentally, irrespective of what their physical age may be, so that a person forty years of age physically—a person who has really lived forty years—may really be only nine years old, so far as his mental development is concerned, and so that person is only a child, and we should call him an imbecile, from the mental standpoint. Now in our society our forty-year nine-year-old has all the rights of society. He can vote, if he is a he,—and in some places if he is a she,—and enjoys all the rights of citizenship. But that type of people often do things which are socially destructive, and they ultimately drift into some of the various institutions caring for their kind, according to the thing that they have done rather than according to the kind of person they are.

Now the paupers also belong very largely to socially inefficient people, speaking of them from the point of view of their social development. That seems at first blush not to be so. Let me give you an extreme instance of what I mean. Suppose a man goes to court and supposes his position happens to be that of a blacksmith and

he can't any longer ply his trade, and he goes to the poorhouse. One naturally supposes that his pauperism is dependent upon the physical injury. But how many people have you known who have lost an arm or leg, or both legs, or perhaps their eyesight, and yet were able to get along and lead efficient lives in the community? Helen Keller comes immediately to my mind,—a young woman now, I think, in the neighborhood of forty years,—who lost her eyesight absolutely and her hearing when she was about three years old, and yet she is not only an efficient member of the community, but is a capable writer and speaker, and very much loved by everybody. I saw her not long ago in Washington. She had been down to see the Adams Memorial. She goes to see things, you know, just like any one else does. She jumped out of the auto, she felt around the base of the statue, and her first remark was, "I have never seen such beautiful azaleas!" And then she felt up further and she remarked instantly upon the trees. She climbed out upon the statue and felt over the face—of that marvelous piece of sculptured work, and in a few minutes she exclaimed, "This should not be here. This ought to be on a battle-field." Perfectly marvelous! And yet she had been blind and deaf from her third year.

Now as to the man who loses his arm. If he goes to the poorhouse, it is because he has not been able, you may say, to make a readjustment; it is because he has lost his nerve; or you may formulate it in any other way you wish. If he had had the mental capacity, he would not have had to go to the poorhouse. So the great number of people who are in our poorhouses are there because of some type or other of mental inefficiency.

The criminal belongs to another type of inefficient individual—a type of inefficient individual positive rather than negative. The so-called insane person usually has not done anything of a positive nature to destroy property or life, but the criminal has done something positive to injure society. Dr. Fernald says at least 25% is a conservative estimate, and I am sure the per cent. is as large as that, or larger—at least 25% would absolutely come within the purview in some degree of feeble-mindedness by our present methods of examination; and when you look at the thing broadly in the way that I am trying to show you now, it is a perfectly proper thing to say that they come within the group of socially inefficient individuals: and socially inefficient must mean some degree of mental defect at its highest level, so that all these groups of socially inefficient individuals belong within the problem of the mental hygiene movement.

What are we going to do with them, and who is to judge? We have two large types of problems to meet, and I am dividing the matter off into two groups. We have two great groups of people, one of which we can say is salvable,—

can be saved,—and the other group cannot be saved. We have another group of people who can be prevented from breaking down in this sort of way, and certain other people who, if they have broken down, can be brought back into a condition of social efficiency—of ability to live in the community; and then we have another very large group who cannot be gotten back into a condition of social efficiency. As to the first group, those who can be saved, those about whom something can be done: to give you an illustration, let us take a child, for instance. Suppose the child is an only child and suppose in addition that he has had some serious illness so that he is more or less crippled. What happens to a child under such circumstances? The parents are extremely solicitous of such a child; they take the greatest care of him, they do everything in the world to protect him, to prevent harsh words from hurting him in any possible way, and so they rear a child who is tender, who is incapable of meeting the ordinary rough problems of life, and who finally when he has his own way to make, finds that he is quite unfitted to do so, and he meets his problems of readjustment with irritability and crossness and attempts to get away from them, and he feels that the world is a pretty tough place to live in and that people are pretty harsh individuals, and that the world is all thumbs down for him.

Now here is a type of case that we see very frequently, a type that seems quite unable to meet the ordinary problems of life in a quiet, effective and efficient way. Now such children as that very often break down, and there the problem of mental hygiene fits right straight into the problem of education. I remember, in a talk that I gave not long ago, I said that we sometimes do a great deal of harm by education. Let us go down into the mining regions of Pennsylvania and here we find a miner who gets three or four dollars a day and lives in a little house and has two or three children. His girl goes away to school and she learns a little algebra, a little French and a little piano-playing, and she has been spoiled for occupying the position into which she was born, while she has not been given the means to rise out of it. Then a good dominie came and took me very much to task for what I had said, and told me that it was right for every miner to have a piano in his household, and that the poor people were entitled to everything that they could get in the way of education. And then I realized that I had not put it quite as clearly as I should, and that I had not said exactly what I had intended to say. If we are going to succeed in our valuation of human individuals, and are going to succeed early enough during the educational period, we have got to learn how to be able to tell what sort of material a person is made of before we crowd them with tasks that they are ill fitted to perform.

Now we know something about the other or-

gans of the body,—bad heart, lungs, etc.,—but we don't know how to value the strength of the mind. We don't know how far we may go in our education in forcing our young people, and we may do them a great deal of damage. But the neurologist and psychologist have asked the question how to determine this very point. We have now what you have heard called vocational psychology, to try to find out what children are fitted for, and educate them along those lines and not try to educate them for what they are not fitted. We cannot solve that problem in a number of cases, but in some the main lines are fairly clear. To the parents of a feeble-minded boy, we may be able to say, "This boy may be taught to run errands and do such simple tasks, but he is only so far developed and he'll never develop any more; that is, his limit is reached, and if you try to push him any further beyond his limit you will soon get into trouble." In the case of normal people the question becomes a more difficult one, and we cannot know how to answer it. But the question has been asked, and the main thing is to ask the question, because as soon as the question has been asked, we can find some way to answer it.

A youngster who has been brought up in a family where the father is a drunkard, and the father comes home at night and raises the old scratch, curses and swears and beats his wife, etc.,—and we all know there are plenty of such cases on record,—never gets the right attitude in the beginning. This youngster, who ought to be raised in a situation where he will look up to his father with respect, look to his father as the source of authority, learns to hate his father for the way in which he acts, beats him and is unreasonable with him, and so such a child grows up into later life and you can see how it comes about that he grows up hating all sources of authority; he hates all forms of restraint, he hates the social institutions which form the controlling situations in which he lives; and such people become the rabid type of anti-social or anarchistic persons—anything you wish to call them—and they shoot and destroy;—they become such individuals. And so mental hygiene is interested in the family situation; it is interested in the social conditions that are brought about and that begin and have their root and source and origin in the childhood of the individual.

Now take the neurotic. A hundred years ago the mother of a household did all the housework, made all the children's clothes, had to weave the cloth that the clothes were made out of, and a hundred other things. Nowadays there isn't a single thing that the mother of those days used to do that can't be done a hundred times cheaper and better, by a corporation around the corner, than she can do it. So to speak, the woman, and the mother of today both, are, to a certain extent, out of a job, and she is looking for some legitimate and adequate outlet for

her energies, and that is one of the reasons for the so-called "woman movement." Mental hygiene is interested in all movements like that because they have their root and make-up, too, in the individuals that go to form society.

Now how about the individuals who can't get hold of themselves; who are so broken and so damaged in one way or other that they can't be sent back into the community as useful and efficient members of that community? We have a duty towards them, and it isn't a simple humanitarian, altruistic duty of love to your brother without any compensation. If it was, I don't believe I should want to talk to you about it, because I don't believe I could impress you with it in a way that would be of any value. I don't believe anybody does anything in this world nowadays without some sort of expected return, and I believe that a great big movement of this sort could not live unless the thing that we were trying to do brought some sort of return to you individually; to you as members of the community; to the community of which you are members, and would return to you in the benefit which all the community derived. Therefore, there are two things that we want to do for these individuals. We want to give them something and we want them to give something back to us, because anything that isn't paid for isn't worth anything. Indiscriminate alms-giving is a vicious principle of humanitarianism and it usually isn't a method of procedure that has back of it any valuable idea. People who give alms to suffering individuals, usually do it to relieve themselves of seeing the suffering rather than to help the individuals. The only way to help people is to do it intelligently, and the real way to help people is to help them to help themselves. So there are two things that we want to do for these unsalvable members of the community. We want in the first place to provide an environment for them in which they can live and find the maximum individual expression that they are capable of.

Now I was talking in Illinois the other day, and Mr. Johnson of the Vineland Institution for the Feeble-Minded was speaking about the feeble-minded problem, and he started off with the general proposition that the danger from the feeble-minded is all a delusion. There isn't any danger from the feeble-minded. The danger is the danger that arises from the unkind and unintelligent things that the people in the community do to the feeble-minded. The feeble-minded person in the community can't get along usually because he isn't let alone. The feeble-minded boy is teased by his companions and bothered and made fun of until he turns around and kills somebody. Then the community says there is a problem. The feeble-minded girl is made use of by some morally unscrupulous individual, and then she brings feeble-minded children into the community. So we'd be all

right if let alone. Mr. Johnson gave instances of this, for example, a feeble-minded girl—a girl in a physician's family—forty years of age. He went to call on the physician and rang the bell. When the maid answered the bell he recognized her as a girl that he had recommended for this position. She had been living in that house, taking care of the children and doing simple tasks, for over twenty years. Living in a place where she was understood, where she was decently treated—100% efficient. If she had been out in society, out in the open, absolutely dependent upon her own resources, among people who did not know or understand anything about feeble-mindedness, her efficiency would have been zero.

There are any quantity of just such feeble-minded people who get along with 100% efficiency, if in the type of environment which our institutions provide. I remember an insane man, for example, who used to go out and dig every day—trenches—a valued worker, working every day. Now digging trenches is worth \$1.50 a day. About once in so often he would stop in the midst of his work, more particularly when he was coming back from work, and jump and stamp and howl and make a tremendous display. He had the idea that the devil was on his back and he was trying to get him off. This thing might happen a hundred times a day, but nobody paid any attention to him. He was crazy, and yet, although he had been so for many years, he was probably 100% efficient, so far as his earning capacity, his capacity to earn an ordinary day's wage, was concerned. Outside of the institution he would have come to grief in fifteen minutes. And so one of the things that society has to do is to provide a proper environment for these people.

A proper environment means a great many things. It means the whole problem of institutional management. A hundred years ago proper environment was locking such a person up in a cell, chaining him to the floor, or beating him to death. But we know now that this is not the best plan, and that it is economically the worst way to deal with these people. You deal with people in that way, and it will cost you twice as much to take care of them, because they are made destructive. We had a woman come to the hospital the other day who came to us with the history of having attempted suicide. She was a criminal from one of the federal prisons. We have not had a minute's trouble with her since she came. They had been watching her every move, repressing her at every turn, but we simply let her alone and gave her freedom to do the thing which she had attempted to do, and which she then no longer had any desire to do.

So, then, the community wants to provide both as a matter of common decency and of economic value, an environment in which these people can find their best personal expression,

and second, it wants to provide an environment where these people can pay back what they are getting from the community; so if we provide an environment, it should be an environment where these people can do something to pay for what the community is giving them. Those are the two general principles with which we have to deal in working with the unsalvable type of mentally defective individuals.

Now the hospital for the insane has a great many functions to perform, one of which is to take care of these unsalvable types, and another is to get well those who can be gotten well; the third is to represent in the community in which it is located the centre of information about all such problems as this, so that the community will feel that it is not an institution absolutely surrounded by walls, but an institution which is willing at all times to reach out in a helpful way in every direction and to all persons in the community in which it is located.

The institution is the natural place and the scientific place where problems in regard to the types of people of whom I have been speaking should be worked out, and they should be worked at until solutions have been reached which are sufficiently valid, sufficiently correct, sufficiently definite and far-reaching to be backed up by the community and formulated in some sort of statute.

The same thing is true of the prison problem. In the prison problem,—and it is largely a mental problem, too,—I think that if we endeavor to correct the mistakes that have been made in shutting up a great many real defectives in prisons, it will help a great deal. In this way we could try to save those who are salvable, and if they are not, prevent them from committing depredations, at least. After these problems have been worked out by the psychologists, then the social workers, and all the different agencies of these various institutions can finish the good work by formulation in the crystallized forms known as statutes, and then they can be generally accepted and then the institutions can carry them out.

I am neither a pessimist nor an optimist; I try to take a middle course. I don't believe that we are ever going to get away from the problem of the mental defective; there is always going to be a problem; but the thing we can do is, perhaps, to make the distance which separates the man at the top of the ladder and the man at the bottom a little bit shorter, but we can shorten that distance only by a concerted, really tremendous effort. But society is advancing. It is going ahead all the time. We have to a certain extent largely solved the general problems of sanitation and hygiene, and we finally come to the disorders of the mind and what to do about them, and that, after all, is the most important of all of them, because upon the conditions of our minds rests whether we are happy or unhappy, whether we are effi-

cient or inefficient, whether we are successful or unsuccessful, and our manner of living is, after all, simply dependent upon our minds.

So then, finally, after all these things are formulated by legislation, we can go on with new problems, always believing that there is something more to be accomplished further along the line. We are never going to be able to solve all the problems, but the most important thing for the individual and for society is to try to solve them. We shall never reach the goal, we sometimes think, but we do it in some cases, and we should not want to do it in all, for the person who has finally accomplished everything to the perfection of his ideals, is usually through with his work and is of no more use in life.

So I want you, if possible, to feel that here is an effort of the very greatest importance that is just beginning now to be born in this present-day society. You have here in Massachusetts one of the best organizations for dealing with the questions of mental disease that there is in the United States. I hope that the citizens will take that individual interest in what that system is trying to do—which is the key-note of success of a democratic form of government; and it is because we want the citizens to take that interest that these meetings are being held, for upon that interest depends the success which any such movement as this can hope to have.

### THE MENACE OF MENTAL DEFICIENCY FROM THE STANDPOINT OF HEREDITY.\*

By HENRY H. GODDARD, PH.D., VINELAND, N. J.,

*New Jersey Training School.*

You have listened to two most interesting and valuable papers on two aspects of the Hygiene of the Child Mind—how to conserve the good qualities<sup>1</sup> and how, by right treatment, even restore those who have begun to lose their natural vigor.<sup>2</sup>

It is my not altogether pleasant duty to discuss with you a less pleasing because less hopeful side of the question. I am to remind you of that group to whom the laws of mental hygiene have little or no application, because their minds are so weak there is little to conserve, and no cure is known. From the standpoint of the child, something can be done to make them a little happier; from the standpoint of society, no amount of mental hygiene can ever render them efficient citizens. Society can, by proper treatment, render them less of a menace than they are naturally; and the ills that we now suffer on account of them, can be largely reduced.

It is estimated that there are from 300,000 to 400,000 mental defectives in the United States.

That is based upon the United States census of 1890, in which the question was asked "Whether defective in mind, sight, hearing or speech, or whether crippled, maimed or deformed, with name of defect." Now if anyone can estimate what proportion of the true number of the feeble-minded would be returned in answer to that question, he will be able to estimate how near the truth is the 200,000 which the census report gives. Three hundred thousand or 400,000 seems to be a conservative estimate.

I am to discuss this topic from the standpoint of heredity. It has not yet been successfully contradicted that two-thirds of this army of 300,000 or 400,000, owe their condition to heredity. A quarter of a million of these people are feeble-minded because their ancestors were feeble-minded. They have inherited the condition just as you have inherited the color of your eyes, the color of your hair, and the shape of your head. There is a tendency in these days to attribute a great deal to heredity. But of this particular thing there seems to be no question. The menace of the problem comes, not from the fact that a quarter of a million inherited their condition, but because they are transmitting that condition to their offspring. Of that quarter of a million feeble-minded persons in the United States, do you know how many are being cared for, guarded and kept from propagating their kind? About 24,000 out of 250,000 are today being cared for in such institutions as you have here at Waverley. The rest are living—their lives, are raising families, and providing abundant opportunity for the exercise of the charitable impulses of numberless generations to come. And that condition of things is getting worse rather than better.

I shall not take your time—it is not necessary—to speak of the bearing that this has on our social problems. You know of that. You have had it presented in several different ways, and there is no finer work, that I know of, than your own work here in Massachusetts by the "Commission for the Investigation of the So-called White Slave Traffic," in which it was found that over 50% of the women were so absolutely and definitely feeble-minded that they might be admitted to an institution like Waverley at any time.

What shall we do? There have been two answers. Some say, "Segregate, shut them up. Keep the sexes apart." We are told that if we could do this for a generation our problem would be largely solved. The two-thirds in which the condition is largely hereditary would be eliminated. I want to assure you that the problem is larger than that. In the first place, looked at from the practical standpoint, we do not seem to be able to segregate. We are taking care of 24,000, and there are at least 250,000 to be cared for. If the State of New York, for example, for its estimated proportion of mental defectives, it would require thirty institutions of 1,000

\* Read before the conference of the Massachusetts Society of Mental Hygiene, Ford Hall, Boston, Nov. 19, 1915.

each. They find it hard to raise money for the three or four institutions they now have. Their appropriations are cut every year. In the State of Massachusetts there are at least 14,000 feeble-minded persons. It would require ten institutions the size of Waverley,—a demand upon the public treasury which we are not willing to meet. I have not found anyone yet who is optimistic enough to think that we shall meet the demand within any reasonable length of time,—a time so short that we can safely rely upon that as a solution of the problem.

Another group of people say "sterilize," and there is a percentage of them who say, "Get a sterilization law on the statute books and you are all right." There are a great many people who think that all that is needed is law. There are now twelve states that have sterilization laws, and there is not one that is making any great use of it. Wisconsin has operated upon a few feeble-minded. The State of Indiana did something in the case of criminals, but at the present time there is nothing being done along that line. The laws cannot very well be made practicable except for those who are in institutions. There is no other solution suggested for these people in the way of care.

If asked what we shall do,—which of these, or what else,—I should say, "Both; and everything else that we can do." In other words, it is a problem that requires our most careful thought and requires the application of every means that we can conceive of. I believe that sterilization might be a great help in a great many individual cases—solving individual problems, relieving a situation where we cannot see any other way to get at it, and I think it will have to come, and have a very much larger application than the laws now provide for. Somehow we shall have to come to the point of authorizing a commission of physicians to carry out this practice wherever, in their judgment, it is advisable. That seems to be the only way in which this method can ever touch the problem to any efficient degree. The present laws apply only to persons in institutions and cannot reach the most important group.

I have said that this quarter of a million, this army of feeble-minded people, are propagating. They are propagating a progeny of feeble-minded at somewhere from two to six times as fast as the intelligent people are propagating their kind. That is another serious part of the problem. I should like to digress from my particular field for a moment to make a suggestion on the other side. It makes one feel pessimistic when we find that the good stock here in New England—the stock than which there is no better in the world—is gradually disappearing for lack of issue. Of one family after another one reads all too frequently, "The last of his family has passed away." We are told sometimes that two children in a family are all that can be properly reared; that it is better to rear

two children and rear them properly than to rear a larger family and rear them badly. If *two children in a family* are all that our best and finest and nobler families can properly raise, *how many children* ought to be raised in a family of these low-grade people? The average in the United States is, for all classes, something less than two, and the average for these defectives is from four to twelve. In that little family that we ran across down in New Jersey, which we call the Kallikaks, you will recall that the good side started from six ancestors. That is to say, Old Martin Kallikak, after he married, had seven children, one of whom died without marrying. From the six who lived and married, sprang all the normal descendants. Martin's illegitimate son, the child of the feeble-minded girl, was the only one on the bad side, and yet today the number of descendants from the illegitimate mating is practically the same as the number descended from the six legitimate children. You can see that it does not take many generations for the progeny of the unrestrained feeble-minded to equal and even outstrip the normal. Our good stock is multiplying very slowly. Our poor stock—the lowest strata of society—multiplies in what might really be called a brutal ratio. If civilization is to advance, our best people must replenish the earth. I think it should be a part of our religion to replenish the world with good, clean people.

But there is still another point in the menace of the mental defective from the standpoint of heredity. Not only are there a quarter of a million people propagating much more rapidly than the general population, but they are propagating according to the Mendelian Law. That law shows that the transmission of traits is much more complex than has been suspected. Those who tell us that if we could sterilize we should eliminate feeble-mindedness in a generation or two, have not considered the method of inheritance of feeble-mindedness. I want to call your attention, briefly, to the difficulties of dealing with inheritance under the Mendelian Law.

There are six possible kinds of matings, giving rise to six kinds of families. If a normal man marries a normal woman, the children are all normal, and out of the six possibilities, that is the only one that is entirely good. Second, if a feeble-minded man marries a feeble-minded woman, the children are all feeble-minded. In this case the only hope is segregation or sterilization of all the children. Third, if one parent is feeble-minded and the other normal, all of the children will be normal, but "simplex," that is to say, they will inherit their normality from only one parent, not from two, which means that while they themselves are normal, *they can transmit their defect*. It will be seen that we could not sterilize any of these under any law that we now have. If they are not

feeble-minded they cannot be segregated, and yet every time they marry there will be some feeble-minded, as you see in the next group.

From a marriage between two people, each of whom has inherited feeble-mindedness from one parent, what do we have? Three normal to one feeble-minded, but of the three normal only one is duplex. Only one child out of four who can never transmit feeble-mindedness. The family comprises, therefore, one feeble-minded person, two that can transmit defectiveness, and one that cannot.

In the case of one of those normal persons who can transmit defectiveness marrying a duplex normal person, all the children are normal, but *one half of them can transmit defect.*

Now the point that I want to make in all this is the enormous complexity of the problem. It is evident that out of all those cases, there are only a very few where we know, or can know, enough to take any action. People who have been reading about eugenics have discovered that there is something in heredity, write to us, stating certain conditions and asking, "Is it safe for me to marry this particular individual?" Up to date I have not had a single case presented to me in which I could say, "If you marry, there is an even chance that your children will be feeble-minded," and yet I have had some cases presented to me that were dubious. We do not know; we cannot tell.

We need to know vastly more than we know today before we can give definite answers, except in the case of marriage between two feeble-minded persons. Now, that being the case, the argument that I want to make to you is: the propagation of the feeble-minded is going on at an enormous rate. If we could do, and if we did, everything that we wanted to do, and that we knew enough to do, we should be getting only at the surface of the problem, and should be sure in only about one case out of the six possibilities. Now if that is the case, my friends, does it seem that we ought to put off attacking the problem until we cannot stand it any longer? Or does it mean that we had better attack it right away? Is it not best to begin hunting for these defective children wherever they may be found? And they can be found in the school, in our juvenile courts, in our almshouses, in our insane hospitals, in our reform schools, in our homes for cripples, in our asylums for the blind,—in short, wherever there is a dependent group there is an undue proportion of these mental defectives.

Some will say, "If they are in almshouses they are being cared for." In reality they are being raised and brought to manhood and womanhood and then sent out, to propagate their kind. Fifty years ago the problem was not as serious as it is today, because these defectives were out in the world by themselves, getting killed by a runaway horse, or falling into machinery, or in some way meeting an

untimely death. Today we are exceedingly careful; we are protecting them in every possible way; we are taking care of them in our institutions and giving them every advantage, and then sending them out into the world—a menace to the rest of humanity.

It would be a dreadful thing if all these problems were solved and we didn't have any people to give our money and charity to. I suppose we should become hard-hearted if we didn't have any to befriend. Perhaps we want to keep enough of these unfortunates so that we can still contribute to their safety and welfare. But, my friends, when we realize the suffering, the terrors, the losses of all kinds that these people unintentionally, unwittingly cause us, we have another side of the problem. The menace of the feeble-minded is not a figure of speech. It is no undue sentimentalism that assures us that we need to take care of this group of people. We need to study them very seriously and very thoroughly; we need to hunt them out in every possible place and take care of them, and see to it that they do not propagate and make the problem worse, and that those who are alive today do not entail loss of life and property and moral contagion in the community by the things that they do because they are weak-minded.

## THE FUNCTIONS OF SOCIAL SERVICE IN STATE HOSPITALS.

By HANNAH CURTIS, HATHORNE, MASS.

*Social Worker, Danvers State Hospital.*

THE different conceptions which people may entertain as to the meaning of social service doubtless depend upon the form of the work with which they are most familiar. The oldest and best known work is that which is connected with settlements, children's agencies, relief societies, industrial welfare work, etc. The best general definition of social service is possibly that of Prof. Peabody of Harvard University. He writes, "Social work is not merely a question of enthusiasm, sympathy, self-sacrifice or money, but it is a question of wisdom, discretion and the scientific interpretation and comparison of facts." This statement defines the work in a very broad sense,—possibly the whole is better understood when a single branch of the work is described in detail; however, it must be well borne in mind that the underlying principles are practically the same in all forms of the work, the aim and purpose being a common

\* Read before the Boston Society for Mental Hygiene, at the meeting of the Society for Mental Hygiene, held at the Hotel Marlborough, Boston, Nov. 6, 1914.

one, namely, that of the betterment of the human family.

One of the more recent developments of social work is that of Medical Social Service, which Dr. Richard C. Cabot thus defines: "Medical Social Service was organized in order to help the patient in his *real need*, of which sickness might be a mere incident. The real need may be his ignorance, recklessness, poverty, discouragement, feeble-mindedness, or loneliness. The social worker understands the real need only when she learns four things: (1) the bodily state of the patient, his diagnosis and prognosis; (2) his mental condition; (3) bodily environment, which includes work, wages, housing and clothing; (4) his mental environment, which includes the influence, good or bad, of family, friends, enemies, and neutral companions. All this involves a sympathetic study of the patient in his home; a personal, intimate knowledge is absolutely essential. This work must be based on real, friendly interest; no fake interest is effectual."

A highly specialized branch of medical social service is that which has recently been established in State hospitals for the mentally diseased. The principles underlying this work are identical with those of the general hospital service, although the methods of the work may differ somewhat, owing to the nature of the disease under consideration. Before plunging into the functions of social service in the State hospital, it might prove beneficial to consider the *hospital* first and to note some of its needs.

One frequently hears the word *asylum* used in connection with the State institutions for the mentally diseased. It is true that this word was formerly attached to institutions of this kind, and rightly so. We understand the word *asylum* to mean a place of refuge or sanctuary to which debtors and criminals formerly fled that they might secure immunity from arrest; the asylum was also an institution in which the aged, destitute or afflicted might find relief and care. Persons who entered the asylum were expected either to die soon or to remain there for life. Our conceptions of State institutions for the mentally ill have been somewhat colored by former methods and customs of the *asylum*; consequently we frequently hear the words "hospital" and "asylum" used interchangeably, many apparently believing them to exist for the same purpose, which is not the case. The word "hospital" conveys an entirely different meaning, mainly because it is different in every respect.

The most vital function of the hospital is curative and reconstructive; it aims to cure or help the patient, and rebuild his life as far as possible. The principle of segregation is not by any means the leading one. The asylum is a place of refuge; the hospital exists for the treatment of the patient and the rebuilding of his life.

Many patients leave the hospital doors to return to their previous occupations; many more to return to home life under more or less supervision. Granting it to be true that the hospital exists for reconstructive purposes, it becomes very obvious that the institution must gather facts with which to reconstruct the lives of its patients, especially so when it becomes necessary to create a wholesome environment to which the patient may return after a prolonged stay in the hospital. The modern medical man realizes the importance and value of the social aspects of disease and their bearing upon the treatment of the patient. As these social aspects are closely intertwined with physical and mental conditions the gathering of social data becomes an important part of the hospital equipment. Then, too, the hospital exists, or should exist, for the benefit of the community in which it is located, and should be in close contact with that community in order that people may easily secure advice as to home treatment or home conditions which have a medical bearing. All this means social work, and doubtless the introduction of social service into the State hospital was the development of the realization of these needs. By means of this department, the hospital is better able to fulfil the purpose for which it is established.

With this brief insight into some of the needs of the hospital and its patients, we may now consider more in detail the functions of social service and what it is attempting to do.\*

There are four main divisions into which the work falls: first, the home-visiting or after-care work; and closely identified with it the systematic visiting of patients who are boarded by the State in private families. This feature of the work is quite important and enjoyable. A personal, intimate knowledge of the patient is thereby made possible. It is a rare instance when coöperation is lacking, as the large majority of patients are highly appreciative of the interest shown by the hospital authorities.

James B., 23 years of age, single, residing in a large city, was a patient at the hospital for several months; mentally he was considered to be below the average. His occupation was that of usher in a theatre. His father is a chronic alcoholic and has served no less than 12 terms in the House of Correction, where he is at the present time. James' mother was also somewhat weak mentally, and therefore unable to understand James and his ways. He had no ambition to work steadily or to learn a trade, preferring to read, or rather to devour, cheap novels, and to smoke cigarettes. He had other wasteful and undesirable habits which were a trial to his family. Soon after he left the hospital a home visit was made and the relatives advised as to methods of home care. Inducements were persistently offered to James to find some kind of steady work, which proved successful, for at present he is steadily employed earning about \$8 a week and considers himself very much of a man,

\* The work described refers to that of the Danvers State Hospital.

for he now contributes a little to his family. Several home visits were necessary, but the family was coöperative, which accounts largely for the results.

Another instance of a somewhat different nature is that of Martha W., who was diagnosed as an alcoholic and mental defective. Martha W. is 33 years of age; of Irish nationality; married; has one son of 8 years. Husband is a waiter and earns good wages. Martha has a sister who is a moral degenerate and is now serving time. Patient was more or less under the influence of this sister, who is considered largely responsible for the drink and drug habits which our patient had contracted. Soon after leaving the hospital Martha's husband declared his inability to care for her properly as she had resumed her former habits. The husband requested assistance; a long interview with him revealed the fact that he had tried harsh and stern measures with his wife, who naturally resented this treatment and turned against him. She possesses an inborn sense of artistic housekeeping, and is strongly attached to her son. Using these as incentives, attempts were made to help patient to overcome her habits through the development of her natural instincts; the husband's coöperation was earnestly sought and obtained. A recent home visit found patient much happier than at time of first visit, more contented with her home and less vindictive toward her husband. Her habits as to the use of alcohol and drugs are not yet overcome, although she uses both in great moderation as far as could be learned.

Numerous cases could be cited illustrating the value and nature of the home visit, in which patients are aided in meeting the difficulties or obstacles which may hinder health or happiness. Friendly advice and encouragement are effective agents in the home-visiting work. In a few cases coöperation is not established, either through fear and ignorance of hospital methods, or because of a low order of intelligence in the family.

Such was true in the case of Isaac G., a young Jewish man suffering from an incurable form of mental disease. After staying in the hospital for some time, Isaac's people desired his release, assuring the physicians that they could give him good home care. A home visit was made several weeks later, but the family were apparently away. Inquiry of a neighbor as to their whereabouts brought forth a story which indicated that Isaac was being abused and neglected by his relatives. These relatives were located by the visitor and interviewed. They volubly declared, with many characteristic gestures, that Isaac was living with a wealthy uncle in New York, who was employing him at a princely salary; their statements during the interview were very contradictory; the mother feigned ignorance of the English language and refused to admit the visitor to the house. A police officer was secured and the house entered amidst voluble protests. The home was in the Jewish tenement district of a large city; the rooms were small and dark, and very disorderly and dirty. In a small rear room, containing a chair, a table and a heap of soiled clothing, we found our Isaac concealed. The room was without heat, in the cold season of the year. From beneath the heap of

soiled bed clothing peered the white, scared face of our Isaac, where his brother had hastily concealed him, for he was absolutely nude. Isaac was emaciated, pale and weak from lack of food and from frequent beatings, which, by the way, were administered to cure him of his delusions, referred to by the family as "foolish talk." He was removed from the house and taken to the station to await help from the hospital in returning him. This is an extreme case, although a true story.

Leaving the department of home visiting, which is most interesting from the educational point of view, we will consider the next division of work,—that of taking medical histories outside the hospital. These generally include the social situation, and when necessary, a description of the home conditions. The medical history is essential in order that a satisfactory diagnosis may be possible. When the hospital physician is unable to secure such information, then the social worker goes into the community and seeks it. It frequently happens that cases of distress are located in this work and alleviated. Robert K. was such a case. No history could be obtained by the physician as no relatives of the patient had called at the hospital. A call at the home resulted in finding our patient's wife in a very poor physical condition, surrounded by a family of three young children, all in school. The eldest girl was apparently developing tuberculosis; the wife was unable to work and the income had ceased when the patient came to the hospital. Relief was secured for the family, as to food, fuel and rent. Winter clothing was provided for the children. Medical aid was secured for the wife and daughter. In a comparatively short time the wife was able to find work and partly support her children. She is practically free from the worry and anxiety which was undermining her health. This is in reality a form of preventive work and quite important.

The third division of the work is that of investigation, to which there are four aspects: (a) investigation of home conditions previous to discharge of patient; (b) investigation of complaints relative to patients; (c) investigation of all applications for patients to board in private families; (d) a special form of investigation which relates to the social aspects of special diseases, as pellagra. Investigation is not as undesirable a thing as many suppose; it is in reality the securing of facts which will benefit the patient, the hospital, and the community. One of the most important forms of investigation is that of the home conditions previous to the discharge of patients from the hospital. This does not necessarily mean a scrupulously clean house, a large income, good food and clothing although these are important. It more specifically means that some responsible person must be in the home who appreciates the condition of the patient and understands, in a measure, how to give the proper home care. If

the patient is unable to work, there should be sufficient income to support him; if he can work, something definite should be done to make work possible; the neighborhood environment should be conducive to health, and the home environment should be such that the patient may be able to keep in as good a condition as when he left the hospital, other things being equal. When home conditions are unfavorable, the social worker should attempt to improve them so far as possible. In some cases this cannot be accomplished. One instance in which it was done successfully will illustrate the work.

John S., 38 years of age; American born; shoe-worker; widower with eight children. This patient had used alcohol to excess for a short time, and this was an important factor in his case. Investigation revealed the fact that inadequate income and sickness had made it impossible for this patient to supply his family with sufficient food. He frequently went to work without food, substituting a breakfast with a glass of beer. Loneliness, discouragement, inadequate income and sickness, were the real needs in this man's case. The house in which he and his family lived was in the midst of a saloon district; the rooms, six in number, were small, meagerly furnished and extremely untidy. Sanitary conditions were far below the standard; five children were sleeping in one small attic room; the eldest, a boy of 19 years, was tubercular in appearance and complained of ill health. A daughter of 16 years was acting as housekeeper, had received no training, and had left school at 14 years of age to help at home. This little flock of motherless children, whose father was a patient at the hospital, was supported by the small wages received by the two older boys, averaging about \$12 a week, \$3.50 of which went to a relative for rent, an exorbitant rent for value received. The inadvisability of returning a patient to these conditions is very obvious. The family was advised to move, and guidance and financial assistance were secured to enable them to do so. A friend promised to see that patient secured work when able to leave the hospital. Urgent appeals are being made for a middle-aged woman to keep house and help in the training and care of the younger children. The family is now living in a new, comfortable tenement in a good neighborhood; they are united and happy. Frequent home visiting will be necessary for some time, for this is an example of reconstructive work previously mentioned.

Other forms of investigation refer to complaints relative to patients, either received directly from them or from some other source. Quite a different form of investigation is made relative to the boarding-out of State patients. All applicants are interviewed. The fundamental parts of this form of investigation refer to the location of the home, the neighborhood and home environment, hygiene of the same. The art of housekeeping is quite important, but not as essential as the hygiene and habits of the family, the plan of home treatment, and the attitude of the proposed caretaker toward her prospective patients. The patients are studied,

their peculiarities noted and, as far as possible, are placed accordingly. These patients are visited systematically and dealt with according to the situation found at the time of visit. They are returned to the hospital when it is advisable to do so.

Another branch of social work in the hospital is that of connecting needy persons with the proper agencies. Many who are committed to the hospital are mothers or bread-winners of families, which means that dependent persons are left without means of support.

Josephine W., 30 years of age; married; American born; good education; became a victim of alcoholic insanity. She was the mother of two boys, aged 4 and 2½ years, respectively. When Mrs. W. came to the hospital these children were left in the care of their father, who was also an alcoholic habitué. This case was referred to the hospital by an outside physician, who considered the situation a serious one. Following an investigation, the guardianship of the children was transferred to a paternal uncle, and they were placed in a good home. Shortly after this it became necessary to commit the father of these children to the hospital, where he remained for several months. Both improved and are out of the hospital on visit. They are both doing very nicely; the man is seeking employment and hopes soon to restore his home and to receive his children. They are eagerly looking forward to this time and sacrificing in order to have the home which they so carelessly destroyed through dissipation. They are trying very creditably to reconstruct their lives and are being encouraged in so doing.

There are many instances when the bread-winners of families become patients, and their families are without means of support; these are connected with relief agencies and a permanent plan formed. Several patients need help in finding employment after leaving the hospital; these are sent to employment bureaux or to special firms, as the case may be. Other patients need to be connected with persons or agencies who will aid them in the moral sphere; others need proper recreation; still others need special physical attention, and are connected with general hospitals for treatment.

The recent establishment of the out-patient clinics is a new field for the State hospital. These clinics are held weekly in the larger cities of the district. Patients who are out on visit are invited to report and to seek such aid as they may require. Through the out-patient clinic the methods of the hospital may be more clearly understood. The advantages of consultation are open to those who are interested or in need of information.

The main divisions of the work are: (1) home visiting or after-care work of patients who are living in the community; (2) the securing of histories outside the hospital when the same cannot be secured in any other way; (3) investigation of various kinds which aid in the care

and treatment of patients in the hospital, and in reconstructive work when they leave the institution; (4) the connection of needy persons with the proper agencies, such as hospitals, associated charity organizations, churches, children's agencies, or whatever. It will be observed that all parts of the work bear upon the social welfare of the patient, which benefits both hospital and community.

Results are sometimes difficult to determine in social work, inasmuch as one deals with silent forces. Reference has already been made to the real needs of patients, which are frequently those of ignorance, recklessness, loneliness, discouragement and poverty. Some results noted are those of the changed attitude of the community toward the hospital, a more intelligent comprehension of hospital methods and purposes, a broader knowledge of mental diseases and their treatment, more reconstructive work in connection with the patients who leave the hospital. The friendly interest taken in the patient's welfare reveals the humanitarian spirit, and reacts favorably upon the patient and his family. The scientific methods of home care enable many to live in the community who would otherwise be obliged to remain in the hospital. The social data obtained for the hospital may prove to be a valuable contribution to hospital service. There is a financial aspect to social service in this line of work, in spite of the fact that the monetary value of a human being cannot be estimated. The expenditures of the hospital must, in the course of time, be lessened somewhat by the increased number of patients who may live in the community under supervision, to say nothing of the preventive work which may be accomplished through this department. Alcoholism and syphilis are contributing factors to certain mental diseases which are largely preventable, and the field for preventive work of this kind looms large before us. Closely connected with preventive work is that of finding employment for the mentally handicapped,—a large and very important part of the work.

The educational feature of social work in the State hospital is a most interesting one; such knowledge as the hospital may gather should be for the benefit of the public and should be within its reach. The social service department acts as a sort of connecting link between the hospital and the community. Interest is aroused and attention is called to mental diseases and the methods of treatment. Social agencies, especially relief agencies, which frequently spend large sums of money in endeavoring to place a sub-normal person on a normal basis, are now taking into consideration the mental condition of persons who seem to be failures. These failures, which frequently have been attributed to "pure encephalopathy," as a worker recently remarked, may now be better comprehended when an examination proves the person

to be of low mentality and utterly unable to do the work of the average man or woman. The bringing together of the hospital and the community is educational to both and beneficial to all. The basis of medical social service is knowledge of the patient and his environment, secured only by a sympathetic study of the patient in his home. This implies that the spirit of social service is altruistic as well as scientific, for as Dr. Cabot states, "The work is based on real friendly interest"—friendship in its truest form, for it is service with the selfish element eliminated.

When one considers that the entire amount of work accomplished is but a mere "drop in the bucket," in comparison to the amount of work that is left undone, the only inspiration that can be derived from this kind of work is to forget the bucket and to remember the "value of the drop" which the bucket contains.

The functions of social service in State hospitals are threefold: to ascertain the real needs of the patients from a social point of view, and to seek for remedies which will alleviate or cure; to obtain such knowledge of the patients as will aid the hospital to render efficient treatment and after-care of all persons who enter its doors; and to extend such knowledge into the community as will be of common benefit to society in the consideration of mentally affected persons and their problems.

The development of social service spells efficiency, and its success depends upon the co-operation of the community through the individual. When the individual realizes that the problem of the hospital is *his* problem, and that the privileges and duties of true citizenship include the earnest and conscientious consideration of the social causes of ill health, then, and not until then, can society hope to realize the full meaning of efficiency and development, whether it be in the economic field or in the intellectual world, or in the moral sphere. No man can live entirely to himself except it be an isolated case like that of Robinson Crusoe, and then not even he could live entirely to himself after his man Friday joined him.

TREATMENT OF BURNS. Report in a recent letter from the French front describes the beneficial use of ambrine in the treatment of extensive burns, especially of the face and hands. Ambrine is a mixture of wax, paraffin, and resin, with a melting-point of 120° F. It is applied to the burned area at this temperature with a brush, or sprayed on with a syringe, and forms an impermeable coating over the entire surface. The peeling off of this layer once or twice daily, and its reaplication, are said to be almost painless, and the method is avowed greatly to minimize scarring. If these statements are confirmed, ambrine may prove of great value in treatment of burns in civil life.

## Reports of Societies.

### NEW ENGLAND PEDIATRIC SOCIETY.

A MEETING OF THE NEW ENGLAND PEDIATRIC SOCIETY WAS HELD AT THE BOSTON MEDICAL LIBRARY ON MAR. 3, 1916; THE PRESIDENT, DR. A. C. EASTMAN, OF SPRINGFIELD, WAS IN THE CHAIR.

The following papers were read:

#### I. THE AMOUNT AND DURATION OF FOMITES INFECTION IN DIPHTHERIA.

By E. H. PLACE, M.D., H. H. AMIRAL, F. D. JONES, M.D., BOSTON.

#### II. SPASMOPHILIA, WITH ESPECIAL REFERENCE TO ITS TREATMENT.

By J. P. SEDGWICK, M.D., MINNEAPOLIS, MINN.

#### DISCUSSION.

DR. ENGLISH (Dr. Place's paper): 'Dr. Place's paper coincides with more recent investigations in regard to the transmission of diphtheria. I think most of the recent investigations are usually or have been along bacteriological lines rather than along clinical lines. Since the diphtheria bacillus was discovered, and since the discovery of antitoxin, the mortality from this disease has markedly diminished. Diphtheria mortality averages in most places from 5-15%, which is still high. The diphtheria bacillus is said to lose its virulence when apart from the body tissues, and, when exposed to sun-light or dryness, dies within a few days. The question may then arise why we have so many fresh cases of diphtheria when we have these known factors? The reason is that so many carriers are going about. It is known that about 1 to 5% of the community are still diphtheria carriers, many of whom harbor the organism for many days after the membrane has disappeared from the throat. This is the chief reason why people, going about with the diphtheria bacilli in their nose or throat, are still keeping up the disease. These carriers who are harboring the virulent or non-virulent organisms are the ones who are transmitting the disease. Some investigators believe that true diphtheria bacilli have a power of losing their virulence even after an attack of diphtheria and under favorable conditions for growth may be transformed again to virulent bacilli. The vast number of bacteriologists claim, however, that true diphtheria bacilli are distinct organisms and that the diphtheroids are not pathogenic and do not cause true diphtheria. Boards of health in the largest cities no longer fumigate houses where diphtheria has been present, and do not fumigate for measles or chickenpox, and in some places not for scarlet fever, because of the fact that the life of the organisms which cause these diseases is short after leaving the body tissues.

We note from the Schick test that there are a number of people known to have natural immunity to the disease, about 80% of infants, 40-60% of children, from one to fifteen years of age, and about 80% of adults. This leaves only a small part of the susceptible people, and it would seem as though with this knowledge that the mortality from the

disease ought to be lower than 10%. The fact remains it has been about the same for the past ten years.

I think one reason why carriers go about transmitting the disease is that the examination of children and of infants, who may have the disease in mild form, is not thorough. Some examine only the heart, lungs and abdomen and do not examine the throat. There is also a vast number of men who do not examine the nose. I had the experience in South Department to take practically all the histories of diphtheria, and it was my experience there that because the child did not complain of a sore throat or have any difficulty in swallowing liquid or soft solid food, the throat was not examined. I think I had taken histories time and time again where for three or four days no thought of the child having diphtheria was present in the mind of the family or even of the physician, until the child began to have a markedly swollen neck, or septic odor to breath, which are characteristic of septic diphtheria.

The examination of noses, I think, is less frequently done. It seems to me that no regard was paid to the possibility of the discharge from the nose as being diphtheritic unless it was a hemorrhagic discharge. A child may have a perfectly clear mucous discharge and that discharge be diphtheritic as often as streptococci or staphylococci.

There is one other investigation which is being done at present, that is the possibility of inoculating the community by giving them small doses of toxin and antitoxin,—mixtures to procure an active immunity to diphtheria which will last much longer than the passive immunity given by antitoxin which is usually three weeks at the most. This is the von Behring active immunity test. This offers great hopes for a lessened mortality, because in the cases thus far reported, an immunity for a year or more may be had. The question of diphtheria mortality still needs and requires a great deal of publicity and education on the part of the public.

DR. WESSELHOEFFT (Dr. Place's paper): A confirmation of the small part played by fomites in the spread of diphtheria is, I think, to be found in scarlet fever wards. Here it is not infrequent to find diphtheria as a secondary throat infection either at the onset or during convalescence. In fact, scarlet fever apparently tends to increase the susceptibility of an individual to diphtheria. Yet in spite of this, and in spite of the frequency of diphtheria carriers in scarlet fever patients, a case of diphtheria in our scarlet wards at Brighton does not mean an epidemic as in the case of the occurrence of measles or chickenpox in these wards. Diphtheritic throats often stay in these wards 24 to 48 hours before they are diagnosed and isolated, yet the disease does not seem to spread to others. Disregarding the consideration of droplet infection in this point, we must admit that the neighboring beds and other objects about the ward must become contaminated before the patient is isolated or barriered. Consequently, I am led to believe that fomites cannot be of much importance in the spread of diphtheria.

DR. PLACE (in closing): It seems to me it is incorrect to consider fomites as playing more than a small part in the transmission of diphtheria, but I think it is a mistake to ascribe so much danger to carriers as is at present done. Dr. English's statement, that from one to five per cent. of the people in the street are harboring the organism, is correct but it has never been proved that these cases harbor

the true diphtheria bacillus in that proportion, or that they are capable of transmitting diphtheria. Diphtheroids are very frequently found, and it is impossible in routine diagnosis to exclude these, particularly in the so-called carrier group. In all studies of carriers, a certain proportion, often considerable, and in some instances nearly a hundred per cent., have been shown to be harborers of non-virulent organisms.

I believe, therefore, that diphtheria is far more frequently contracted from a patient ill with the disease, particularly the mild type, and especially when the nose is involved, than from carriers.

DR. TALBOT (Dr. Sedgwick's paper): We speak of spasmophilia and of the spasmophilic disturbance in a very loose manner, and I note that Dr. Sedgwick brings in the question of asthma into this group. I haven't done any work on electrical irritability, so I cannot speak on that phase of the subject, but I feel that a large number of cases of asthma can be explained by anaphylaxis. Many other men feel the same way I do, and the reason we feel so is that a specific skin test to various proteins can be obtained. Furthermore, when such a food is ingested or the powder of such a protein is inspired, an attack of asthma immediately follows in a sensitive individual. It would seem to me that the heightened irritability which Dr. Sedgwick gets in these cases was probably secondary or incidental in cases of asthma.

I want to ask Dr. Sedgwick whether he has tasted calcium chloride; I have tasted it and I wonder how these delicate babies can retain it.

DR. WEBSTER (Dr. Sedgwick's paper): I feel that Dr. Sedgwick's paper is very valuable. I should like to ask Dr. Sedgwick if he considers it possible that the beneficial action of calcium chloride is due to the prevention of intestinal fermentation? Also I should like to ask him if he has found calcium chloride particularly constipating?

DR. MORSE (Dr. Sedgwick's paper): I haven't anything to add to the discussion of Dr. Sedgwick's paper except that I am surprised at the size of the dosage given to these infants.

DR. LADD (Dr. Sedgwick's paper): In Eschscholtz's tabulation of 240 cases of tetany, a strong seasonal variation was shown, the cases increasing from November to April, as follows: November 21, December 16, January 29, February 51, March 59, April 45, May 10, with only occasional cases from June to November. Did Dr. Sedgwick observe such a seasonal variation in his cases, and can he explain this incidence of the disease?

It has also been claimed that peripheral nerve irritability can be diminished either by increase in calcium salts or by diminution of sodium salts. Has Dr. Sedgwick made any observations in his cases as to the effect of the reduction of sodium salts intake on the electric irritability of the peripheral nerves?

DR. DUNN (Dr. Sedgwick's paper): It is very hard to discuss a subject that Dr. Sedgwick has studied so thoroughly. It seems to me if any objection can be raised at all as to the conclusions drawn in Dr. Sedgwick's paper, it is that it is very difficult to draw conclusions as to therapeutic results in any diseased condition which has no normal or established course.

I have had recently at the Infants' Hospital several cases of spasmophilia which have been studied on the basis of such symptoms as tetany and the

various signs of nervous irritability which can be found on ordinary physical examination. Many come in with the history of repeated convulsions for long periods of time, and after entrance to the hospital, without treatment, have no more convulsions. Other cases come in with the same history and continue to have convulsions steadily for a long time after entering the hospital and then suddenly stop. Many cases stop having convulsions and showing signs of spasmophilia abruptly without any relation to treatment. It seems to me that cases of spasmophilia are apt to run a very irregular course. There are so many spasmophilic cases of short duration that it is extremely difficult to draw conclusions as to the probable cause of the sudden cessation of the symptoms, or attribute the result to the therapeutic measures employed.

The fact that the calcium metabolism in spasmophilia bears a close resemblance to that of rickets is of great interest. I am not so familiar with the work done on spasmophilia as I am with that done on rickets because I have been going over the subject of rickets lately. I am very strongly inclined, as far as rickets is concerned, from the evidence I have been able to gather, to believe that rickets is due not to diet, but to faulty hygienic surroundings. In spasmophilia I used also to think it was due to the diet, but now I do not think that the relation to diet is very definitely established. I am more inclined to believe that spasmophilia also is very commonly associated with faulty hygienic surroundings, and that this is an important contributory cause. The disturbance of calcium metabolism is, like the tetany, a result rather than a cause, and I am very doubtful whether spasmophilia can be influenced by the giving of calcium any more than can rickets.

DR. SEDGWICK (in closing): In regard to the seasons having effect upon the occurrence of spasmophilia, I would say I think the occurrence of this condition undoubtedly varies with the seasons. The manifestations are much more frequent in the early part of the year. I do not think all asthma is spasmophilial.

I do not believe that the beneficial action of calcium chloride is due to prevention of intestinal fermentation.

I find that the administration of calcium chloride is at times associated with constipation.

## Book Reviews.

*The Medical Clinics of Chicago.* Philadelphia: W. B. Saunders Company, May, 1916.

The May number continues the Medical Clinics with the same methods of presentation. The special cases discussed are always interesting. In this particular number there is a good discussion of the Allen Treatment of Diabetes with illustrative specimen diets.

The well-rounded presentation of some clinical subject is apparently being developed by the Medical Clinics. When backed up with case reports, the combination ought to be of more interest and value than the presentation of case reports alone.

# THE BOSTON Medical and Surgical Journal

Established in 1812

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, AUGUST 24, 1916

## EDITORS.

ROBERT M. GREEN, M.D., *Editor-in-Chief.*  
GEORGE C. SMITH, M.D., *Assistant Editor.*  
WALTER L. BURRAGE, M.D. *For the Massachusetts Medical Society.*

## COMMITTEE OF CONSULTING EDITORS.

WALTER B. CANNON, M.D.  
HARVEY CURRIE, M.D.  
DAVID L. EDSELL, M.D.  
REID HUNT, M.D.  
ROGER L. LEE, M.D.  
ALLAN J. McLAUGHLIN, M.D.  
ROBERT B. OSOODE, M.D.  
MILTON J. ROSENBAUM, M.D.  
EDWARD C. STREETER, M.D.  
E. W. TAYLOR, M.D.

## ADVISORY COMMITTEE.

EDWARD C. STREETER, M.D., Boston, *Chairman.*  
WALTER P. BOWEN, M.D., Clinton.  
ALGERNON COOLIDGE, M.D., Boston.  
HOMER GAGE, M.D., Worcester.  
JOEL E. GOLDSWORTHY, M.D., Boston.  
LYMAN A. JONES, M.D., North Adams.  
ROBERT B. OSOODE, M.D., Boston.  
HUGH WILLIAMS, M.D., Boston.  
ALFREDO WORCESTER, M.D., Waltham.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.56 per year for all foreign countries belonging to the Postal Union.

An editor will be in the editorial office daily, except Sunday, from twelve to one-thirty p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager.*

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

## DEATH OF DISTINGUISHED SURGEON.

It is with regret that the JOURNAL records the passing of one of the best-known surgeons of this country. The sudden death from heart trouble of Dr. John B. Murphy of Chicago, at the age of 58, takes from American medicine the services of one of its leaders. Dr. Murphy was born in Appleton, Wisconsin. He graduated from Rush Medical College in 1879, and as Professor of Surgery in Northwestern University, and Surgeon of the Mercy Hospital in Chicago, he occupied an important position in medical education in this country. He was a general surgeon of ability and originality. Among his contributions to surgery, the Murphy button for intestinal anastomosis and the importance of enteroclysis in infections of the peritoneum are, perhaps, the most familiar. His work with bones and joints is almost of equal importance.

Dr. Murphy was president of the American Medical Association in 1913, and the same year

was elected president of the Clinical Congress of Surgeons of America.

He held the degree of LL.D. from Illinois, and that of Doctor of Science from Sheffield, and was a Fellow of the Royal College of Surgeons. He was recently knighted by Pope Gregory for his researches in surgery.

Last year he organized an American unit to serve with the British Army in France. His death closes the career of a really great surgeon.

## MENTAL DEFICIENCY AND ITS REMEDY.

THE present issue of the JOURNAL contains a group of papers, by well-known experts, on various aspects of mental hygiene. Perhaps the most immediately practical of these is that with which Dr. Goddard deals as "the menace of mental deficiency from the standpoint of heredity." The essence and importance of this menace lie in the relatively rapid propagation of the feeble-minded compared with other classes in the community. Formerly, when all stocks were equally prolific and the mentally deficient were more exposed to eliminative accidents, natural process served better to maintain a balance. Now, as Dr. Goddard points out, the feeble-minded are more protected by society from disaster; and the steadily declining fertility of superior stocks tends to destroy this advantage. Optimists believe that the relation will yet right itself; but there seems, nevertheless, occasion for very genuine and serious concern, unless additional measures are taken to correct the disturbance of evolutionary process created by modern protective measures, which favor the survival of the unfit, and by modern practice which limits artificially the number of fit who survive.

Broadly speaking, such corrective measures may be of two kinds.—those which tend to restrain the inferior, and those which tend to increase the superior, stocks. Doubtless both of these should be applied. Dr. Goddard naturally emphasizes the former, but he calls distinct attention also to the latter, which, as the positive side of the picture, perhaps deserves even more iteration. One of the evils of so-called birth-control, of which so much is heard, is that it affects the wrong end of the scale. What is needed is an awakening race consciousness, or perhaps one would better say, human consciousness, which shall realize the duty of suppressing

the undesirable and augmenting the desirable stocks. This is the only type of artificial which can properly supplant natural selection. This is true aristogenics. But for its realization concerted conviction is essential. If the present European War has yet shown the world anything, it is, as Dr. Putnam points out, that highly organized social efficiency is indispensable for the ultimate success of civilization and attainment of human ideals.

## POLIOMYELITIS AND ITS TREATMENT.

DURING the past week there has been a steady continuance of the various epidemics of poliomyelitis in the United States, and several new foci of the disease have developed. On August 19, the number of cases in New York City reached a total of 7006 with 1597 deaths. In New York State, outside New York City, there were, up to Aug. 11, 881 cases and 80 deaths.

In Massachusetts, the total number of cases on August 19 was 128, of which 17 have been in Boston, 11 in Westfield, and 21 in North Adams. In New England, outside Massachusetts, there have been three cases in New Hampshire, 41 in Rhode Island with 7 deaths, and 238 cases in Connecticut with 37 deaths.

Outside of New York and New England, there had been on August 11 over 1300 cases in New Jersey, 212 in Pennsylvania with 54 deaths (an unusually high percentage), and 40 in Chicago. On August 11, Dr. Samuel G. Dixon, health commissioner of Pennsylvania, in the following letter notified Dr. Allan J. McLaughlin of Massachusetts, that the Commonwealth of Pennsylvania had established quarantine against all exposed children from beyond its borders:

"The Commonwealth of Pennsylvania this day placed quarantine against all children under 16 years of age coming from outside the commonwealth, who have had, or have been in contact with infantile paralysis, or who have been living in premises in which there is or has been a case of infantile paralysis during the present epidemic. Other children less than 16 years of age from any stricken district will be held under observation. We trust you will advise all officers of railway stations to warn those affected by this regulation who may desire to come into Pennsylvania.

"I shall be greatly indebted to you if, when your state officers or local health officers in the state report as to the condition of the health of children under 16 years of age, you will have

them give specifically the facts with reference to probable exposure by being in direct contact, a resident in the same dwelling in which a case is under treatment, or if they reside in a stricken district. These facts will be required by the department officers in order that the inconvenience of restricted movements and supervision may not be imposed."

Mr. Richard T. Crane, Jr., of Chicago, has offered a reward of \$25,000 to the physician who, within the next year, shall produce the best cure or preventive of poliomyelitis, the award to be determined by a majority vote of the American Medical Association.

On August 10, a meeting of prominent residents and physicians of Nassau County was held in Roslyn, L. I., at which the sum of \$40,000 was subscribed towards a fund of \$100,000 to combat poliomyelitis throughout the United States. It is proposed to establish a laboratory for this purpose in charge of Dr. George Draper.

In Massachusetts, Dr. Walter H. Brown, epidemiologist for the State Health Commission, and an officer of the United States Public Health Service have been detailed to make an eight weeks' field investigation of the disease in this state. Dr. W. H. Frost, of the Public Health Service, has been detailed to coöperate with local officials in a similar research in New Jersey. Meantime, a national conference of state and territorial officials was held on August 17 in Washington, D. C., under the auspices of the United States Public Health Service, to standardize methods of combating poliomyelitis throughout the country.

In last week's issue of the JOURNAL, we commented editorially on two recently suggested methods of treating poliomyelitis, by intraspinal injections of adrenalin and of quinine and urea hydrochloride, respectively. Another new method which has recently been employed in New York is the use of immune serum from patients recovered of the disease. The Department of Health of the City of New York has issued the following circular statement about this so-called treatment of poliomyelitis:

"Among the various methods advocated for the specific treatment of poliomyelitis, several deserve mention as being based on sound scientific principles. One of these consists in using the fluid withdrawn by spinal puncture in intraspinal injections, subcutaneously or intracranially, into the same patient. This method is based on the assumption that the spinal fluid withdrawn from the patient contains the virus of the disease.

ease, and that the virus injected subcutaneously or intramuscularly will stimulate the production of antibodies which will aid in overcoming the infection. In other words, the method is one of active immunization.

Another method consists in treating the patients by means of spinal injections of blood serum derived from persons who have recovered from poliomyelitis. This is based on the assumption that the blood serum of convalescents contains antibodies which will aid in overcoming the infection.

Since it is known that the withdrawal of spinal fluid is in itself frequently followed by a marked improvement of those ill with poliomyelitis, a series of patients has been treated merely by spinal puncture (withdrawing spinal fluid) without any injections. In a number of instances this has been followed by a striking improvement, possibly through the relief of excessive intraspinal pressure.

The physicians in charge of hospital patients are unable to say what value, if any, the foregoing treatments actually possess. It will be only after very careful comparisons between the different series of patients now being treated that any just estimate can be made. Not all of the patients are being injected. Careful records are being kept so that the results obtained in the injected cases can be compared with those in the non-injected cases."

In another column of this issue of the JOURNAL we publish also, in full, the circular of instructions which has been issued by the Department of Health of the City of New York to field workers, regarding procedure for the control of poliomyelitis, to which attention is particularly directed.

## MEDICAL NOTES.

**CHOLERA ABOARD A JAPANESE STEAMER.**—Report from Yokohama on August 3 states that the Japanese steamer *Hacai Maru*, bound from the Orient to Tacoma, Wash., has been indefinitely detained at that port on account of the occurrence of 15 cases of Asiatic cholera, with four fatalities, among steerage passengers.

**PREVALENCE OF MALARIA, MENINGITIS, PELLAGRA, SMALLPOX, AND TYPHOID FEVER.**—The weekly report of the United States Public Health Service for August 4, 1916, states that during the precedent month of June there were reported in Mississippi 12,878 cases of malaria, 1453 of pellagra, 825 of typhoid fever, and 92 of smallpox. In Virginia during the same period, there were 956 cases of malaria, 341 of typhoid, 65 of pellagra, 44 of smallpox, and 31 of cerebrospinal meningitis. There were 180

cases of smallpox in Kansas, and 273 of typhoid in Ohio.

**DECLINE IN DRUG PRICES.**—Report from New York on August 8 states that there has recently been considerable decline in the price of various drugs whose cost had previously been increased on account of the European War.

"Among the articles on which lower prices were established are antipyrine, Russian cantharides, cinchona bark, Newfoundland cod liver oil, glycerine, cream of tartar, epsom salt, Japan wax, mercury in flasks, as well as numerous botanical drugs and essential oils. Among the more important revisions are a sharp decline in glycerine, and a reduction in quicksilver. Quinine meets a fair inquiry and second hands report a firmer market, with the inside price a shade higher. Menthol is firm, but nominally unchanged.

"Opium is quiet and the undertone barely steady at \$10.90 per pound for the gum, in cases. Powdered and granular opium are unchanged at \$12.05 per pound.

"The arrival of 63 cases of quinine from Java, reported 68 cents, appears to be the inside quotation. Manufacturers' quotations are unchanged on the 75 cents basis. Imports of cinchona bark into the United States for the eleven months ending with May amounted to 3,780,540 pounds, as against 3,436,381 pounds for the corresponding period a year ago."

Report from St. John's, Newfoundland, on August 9, states that there has been a sharp decline from the expected price of cod liver oil.

"Newfoundland dealers in cod liver oil fear they must face a loss of about \$1,000,000 as a result of changed conditions in the market this year. Germany last year bought the Norwegian output of this product and the price of Newfoundland oil ran up from 50 cents to \$2.50 a gallon. Expecting big profits this season a large number of persons entered the cod liver oil business in Newfoundland. Their hopes were dashed when the British and French Governments succeeded in obtaining this year's Norwegian output, forcing a 50% cut in market prices. As the dealers bought the raw material at high cost, they must stand a heavy loss."

**HOSPITAL GIFT.**—The Memorial Hospital of the Medical College of Virginia has recently received from citizens of Richmond a gift of \$250,000 to be used for the addition of a nurses' home, a contagious ward, and a new ward for negroes.

**DIPHThERIA IN WATERTOWN, MASS.**—The rapid development of some 25 cases of diphtheria in a congested area in Watertown has necessitated unusual precautions to prevent the dissemination of the disease. A cordon of police has been placed about the infected area, and antitoxin has been administered to every one exposed to the disease.

## EUROPEAN WAR NOTES.

**COMMENDATION FOR AMERICAN AMBULANCE CORPS.**—Report from Paris states that the American Volunteer Motor Ambulance Corps has recently been commended in French General Orders in the following terms:

"General Order No. 135.

"By order of headquarters, the general commanding group D cites the American Volunteer Motor Ambulance Corps, Richard Norton, commanding:

"Because for more than twenty months this ambulance corps has manifested the most complete spirit of devotion to its work and duty. Because it has rendered the very greatest services to the army division to which it is attached in succoring the wounded in the best possible manner. There is not one of its members who is not a model of cool courage and self-sacrifice. Many of them have been wounded.

"The General Commanding Group D.

"Mangin."

**DISTRIBUTION OF RED CROSS RELIEF.**—Report from Washington, D. C., on August 8, states that up to July 1, 1916, the American Red Cross had distributed in Europe, since August 1, 1914, relief supplies to the total value of \$1,327,663, of which \$1,002,022 went to the allied powers, \$310,732 to the central empires, and \$1909 to neutral nations.

"An analysis of the organization's work since the outbreak of the war shows that up to the end of June, supplies worth \$365,594 had been sent to France; \$223,439 to Serbia; \$127,711 to England; \$122,029 to Germany; \$116,561 to Belgium; \$114,410 to Russia; to Turkey; \$8950 to Poland; \$3391 to Bulgaria; \$3092 to Syria; \$2256 to Armenia and \$600 to Mesopotamia.

"Supplies remaining on hand July 1, totaled \$79,047 of which \$25,448 was destined for the central powers; \$12,620 for the allied powers and \$11,766 for other countries, the remainder being undesignated."

## MEXICAN NOTES.

**HEALTH OF AMERICAN TROOPS.**—Dr. Richard P. Strong, of the Harvard Medical School, who recently made a visit of inspection to the encampments of United States troops along the Mexican frontier, has made, in part, the following report to the acting surgeon general, relative to sanitary conditions there observed.

"Reply to your telegram, found sanitary conditions in encampments both of the national guard and regular troops along border and in Mexico, on the whole, in remarkably good condition. In majority conditions excellent and only in a few camps of national guard were there minor details capable of improvement, which, however, were being rectified. In some of the camps of regular troops which have been

occupied in the neighborhood of a year, conditions were excellent. Water supply as being employed in all camps safe. So far as could ascertain, food of good quality and sufficient in amount. Health of troops on the whole excellent, with no prevailing infectious disease. Some of men suffering from effects of exposure to sun, but majority appear to be becoming acclimatized. Sanitation of the various camps is being most efficiently looked after by medical officers of the regular army corps, and if present measures employed are continued in force, there should be no reason to fear epidemics of infectious disease among these troops. Climatic conditions also not favorable for development of epidemic disease in camps at present time. Believe that the regular medical corps deserving of very high praise for the manner in which they are supervising sanitary matters and particularly so because of rapid mobilization of such large number of troops. Think medical corps may become overtaxed, however, and would recommend increase which will certainly be necessary in case of increased demands. Sanitary conditions in Pershing's encampments in Mexico and condition of men excellent."

**MEXICAN RELIEF FUNDS.**—In response to requests from readers we are glad to reprint from the Boston Transcript the following directory of Massachusetts relief funds for troops on the Mexican border and in camp:

*Boston-Metropolitan Chapter, Massachusetts Red Cross*—Eliot Wadsworth, chairman, Miss L. A. Sewell, secretary, 83 Newbury street, Boston. Sends supplies to militia on Mexican border and regulars in Mexico.

*Eighth Massachusetts Regiment Emergency Committee*—Henry Parkman, treasurer, 36 Temple Place, Boston. Collects and forwards essentials.

*Episcopal Chaplains' Fund*—C. C. Payson, treasurer, 18 Post Office Square, Boston. This fund is to purchase comforts to be dispensed by chaplains at Border.

*Essex County Chapter, Massachusetts Red Cross*—Miss Louisa P. Loring, secretary, Pride's Crossing. Sends supplies to militia on Mexican Border and to regulars in Mexico.

*Massachusetts D. A. R. Relief Committee*—Mrs. G. M. Baker, treasurer, Concord. With money collected, this committee makes comforts for militia.

*Massachusetts Red Cross Base Hospitals' Fund*—Allan Forbes, treasurer, 33 State street, Boston. This fund is to provide equipment and maintenance for three Boston base hospitals and 1 hospital columns.

*Massachusetts Volunteer Aid Association*—George C. Lee, treasurer, 50 State street, Boston. A committee working to provide support for families of militia at Border, who are in need.

*Mrs. John A. Pearson Fund*—For purchase of comforts for regular troops in Mexico. Mrs.

J. A. Pearson, treasurer, 29 Melville avenue, Dorchester.

*Ninth Regiment Association*—Joseph H. O'Neil, treasurer, 85 Devonshire street, Boston.  
*Special Aid Society Emergency Fund*—To provide necessities for militia in mobilization camps. Mrs. J. Montgomery Sears, treasurer, 12 Arlington street, Boston.

*Surgical Dressings Committee of the National Civic Federation*—"Home Relief Work" in the preparation of dressings for the Massachusetts Red Cross base hospitals. Old Colony Trust Company, treasurer, 17 Court street, Boston.

#### BOSTON AND NEW ENGLAND.

**MASSACHUSETTS GENERAL HOSPITAL.**—The Massachusetts General Hospital has recently established the practice of sending daily in pleasant weather to Oak Island, Revere, ambulatory patients for open-air sun treatment.

The outbreak of diphtheria among nurses at the Hospital, noted in last week's issue of the JOURNAL, is now at an end. The total number of cases was 38. There were no fatalities.

**DENTAL REGISTRATION.**—It is announced that at the semi-annual examination held last month by the Massachusetts State Board of Registration in Dentistry, 125 candidates passed successfully, including two women.

**CONTROL OF GLANDERS.**—It is reported by Dr. Lester H. Howard, commissioner of the Massachusetts State Department of Animal Industry, that during the past year, since the closing of all public watering-fountains, there has been a diminution of 53% in the number of horses killed in this commonwealth on account of infection with glanders.

**BOSTON BABY HYGIENE ASSOCIATION.**—The recently published monthly report of the Boston Baby Hygiene Association states that during July, 2198 babies were cared for, the largest number yet recorded.

"There were 78 medical conferences held, with a total attendance of 3037, which is the largest monthly conference attendance on record. The average conference attendance for the 12 stations was 39. Three stations, Charlestown, Lincoln House and the Health Unit, had an average attendance of 55 babies. The nurses made 6071 visits on babies registered, and over 1000 visits on eligible and older babies. This is also a record for a single month.

"The 2198 babies cared for averaged over one visit to the physician at a conference, and over two home visits by the nurses. Although 126 more babies were cared for than in July, 1915, 16 fewer babies were referred to physicians or hospitals on account of illness.

"It is announced that the Association tentatively established on August 7 a new milk sta-

tion in the building of the Boston Young Men's Hebrew Association at Grove Hall, Roxbury.

"This new station has been made possible by the contributions of people specially interested in the welfare of the babies of that neighborhood. The station is opened with money enough in hand to conduct it for only three months; but it is the feeling of the Association that, when the results of its work are seen, there will be no difficulty in raising enough funds to make this station a permanent one."

**HOSPITAL REQUESTS.**—The will of the late Mrs. William Wilkins Warren, which was filed in the Boston Probate Court on August 5, contains bequests of \$5000 each to the Brookline Free Hospital for Women, the Perkins Institution for the Blind, and the New England Hospital for Women and Children, and \$2000 to the Children's Hospital, Boston.

#### Miscellany.

#### INSTRUCTIONS TO FIELD WORKERS REGARDING PROCEDURE FOR THE CONTROL OF POLIOMYELITIS.

THE following instructions to field workers in poliomyelitis have been issued by the Department of Health of the City of New York.

##### I. GENERAL INFORMATION.

1. *Incubation Period.*—The incubation period of the disease and the quarantine period applying to children under 16 years of age who have been, but no longer are, exposed to infection, has been placed at 14 days.
2. *Quarantine.*—In all families where a case of poliomyelitis has occurred, all the children under 16 years (except those who have had the disease) are to be quarantined in the home until two weeks after the termination of the case by death, removal or recovery. The patient, whether at home or in hospital, must be quarantined for eight weeks from the onset of the disease.
3. *Placards.*—Every house, without exception, is placarded. On private houses, one placard is placed on the street wall of the house and one placard is placed on the door entering room the patient occupies. On tenements, three placards are used; one for the street wall, one for the wall of the entrance hall and one for the door of the apartment. All placards are dated.
4. *Removal to Hospital.*—No case is to be left at home unless the following conditions are complied with:

- a. There must be a physician in attendance daily and regularly.
- b. The person attending patient must obey quarantine regulations and must not do any housework, marketing or perform any other household duties.
- c. The patient and the attendant must have a separate room.
- d. All the windows of this room must be screened.
- e. The family must have a separate toilet for its exclusive use.
- f. Quarantine regulations must be strictly observed by the patient and the other children of the family, if any. When the disease occurs in the premises or families of food handlers, the employment of such person or persons at this occupation is forbidden, unless they occupy entirely separate apartments, for a period of two weeks after the removal, recovery or death of the patient.
- g. *Disinfection and Renovation.*—The personal and bed linen of the patient must be properly disinfected and, after removal, recovery or death of the patient, complete renovation of the premises is done.

## II. DUTIES OF INSPECTORS.

Cases are reported by physicians', nurses', social workers' and citizens' complaints, and all are visited at once by inspectors, even those reported by physicians with request that they be admitted to hospital.

The janitor or his representative must be seen in every instance and notified that he will be held personally responsible by the Department for keeping quarantined children in the family premises, and seeing that placards are not removed.

If the inspector makes or confirms the diagnosis, the Borough Office of the Department is notified and by it the ambulance is summoned, if removal is indicated. The average time required from the time of report until the time of admission to hospital, is now about eight hours. In every case the inspector leaves a hospital admission slip properly and fully filled out.

All cases of questionable diagnosis are seen at once in consultation with the Borough or Chief Diagnostician and whenever it is required, spinal puncture is made and laboratory report submitted by the staff of the Research Laboratory. A full history is recorded on a special card (Form 316-V) for each assignment covered by inspectors.

## III. DUTIES OF NURSES.

Nurses at once visit every case so reported, to instruct the family regarding quarantine, and every other family in the house:

- a. that a case of this disease is in the house;
- b. that the other children of the family in which the disease has occurred will be quarantined, but that, should they fail to observe quarantine, that fact will be immediately reported to the Department of Health and steps taken to enforce quarantine by a summons to Court, if necessary;
- c. regarding home cleanliness, personal hygiene, the danger of infection by flies and any general measures which may be taken to prevent infection;
- d. to report at once to the Branch Office any suspicious illness of children or any cases of poliomyelitis, especially if they are not under the care of a physician.

Nurses must see the janitor or his representative on first visit, and repeat the instructions given by the inspector.

Patients remaining at home are visited at least twice weekly for the maintenance of quarantine, and oftener if necessary. After removal, recovery or death of the patient, nurses issue renovation notices, following these up by visits until complied with.

## IV. DUTIES OF THE SANITARY POLICE.

These officers visit frequently, daily if necessary, premises in which patients have been allowed to remain, to enforce quarantine and to affix or replace placards. They serve the summonses when quarantine regulations are broken, and appear in court.

## V. ALLIED SOCIAL, NURSING AND LAY WORKERS.

Under the direction of the Department of Health, nurses supplied by the Charity Organization Society, the Association for Improving the Condition of the Poor, the United Hebrew Charities and Henry Street Settlement, and lay visitors from various social service organizations, are engaged in an intensive house to house, family to family survey in infected districts, to verbally instruct them regarding the disease and its prevention by personal and domestic hygiene and to report illness, especially of children, and insanitary conditions.

The Metropolitan, Prudential and John Hancock Insurance Companies are distributing literature by their visitors who will also report illness and insanitary conditions.

## VI. ROCKEFELLER FOUNDATION.

Physicians and nurses supplied by the Rockefeller Foundation, under the direction of the Department of Health, follow up the ramification of all reported cases of poliomyelitis, and also doctors to cause inspection, and report suspected cases.

## Correspondence.

## A GENERAL PRACTITIONER'S OPINION.

*Mr. Editor: Hoccus, stans in tecto domus, lupo practerenti maledixit. Cui lupo, "Non tu," inquit, "sed tectum mihi maledixit."*

Not Dr. Richard Cabot, but his exalted position, reviles us. The numerous *non sequiturs* in the lay articles of Dr. Cabot recall many memories of the days of my youth when I was a junior master in a large public school. Quite boyish is his account of how the mercenary surgeon was balked of his prey. "Under my treatment she recovered." When asked how soon the surgeon should be called upon in a case of gastric or duodenal ulcer, Dr. W. J. Mayo was accustomed to reply, "After the patient has had nine medical cures."

The story of the hide-bound medical truth-teller, as told in the July *Harvard Theological Review*, seems to have been excessively abridged. I first heard this story over two years ago. In making this shocking and false diagnosis of tuberculosis, and in announcing it to the patient, the able and experienced, the honorable and honored general practitioner who had been in charge of the case was wholly ignored. But, at once, on the same day, as soon as the general practitioner heard of it, he stated that, though he did not know exactly what the matter was, he did know one thing, that it was not tuberculosis.

Not very many years ago a surgical friend of mine had a sponge left in his abdomen by a surgical friend of his. The mistake was discovered a few weeks later. I do not know whether "there was much good-natured chuckling," or whether the victim "readily forgave the mistake." As between mental and physical suffering, I much prefer the physical. I have had above average personal experience of both.

A few weeks ago the *Transcript* had an editorial headed, "Dr. Cabot and the Other Doctors." And that is about the alignment. I am very sure that Dr. Cabot wholly misrepresents all save a very small and negligible fraction of the doctors. Dr. Cabot "is a man of faith, who has surrendered his reason, and whose unbounded vanity always makes him see things with prejudiced eyes." "He has lost the faculty of impartial judgment." "He never keeps his mind open, and is not an earnest inquirer of truth." "He is satisfied with what poor fragments of philosophical patchwork he has got, and to him that is the whole truth." Thus equipped, he dashes off articles and addresses, with misinterpreted and distorted facts, with innuendos, insinuations and slanders. He is as ignorant of the work and problems of the general practitioner as though he lived in China or Thibet. He can have but the most elementary conception of the bodily changes due to emotions. I doubt whether he has even a superficial acquaintance with the splendid work being done by the Metropolitan Life Insurance Company on Community Morbidity and kindred subjects. Nevertheless, "priding himself on the possession of the art of critical research, he misuses the inductive process and generalizes too widely and emphatically on very sparse facts and cunningly puts his conclusions before the world without any sense of shame."

FRANK E. BATEMAN, M.D.  
Somerville, Mass., August 9, 1916.

## SOCIETY NOTICES.

AMERICAN ASSOCIATION FOR STUDY AND PREVENTION OF INFANT MORTALITY.—The Seventh Annual Meeting of the American Association for Study and Prevention of Infant Mortality will be held in Milwaukee, October 19-21, 1916.

The subjects to be discussed include:

Governmental activities—Federal, State and Municipal—in relation to infant welfare.

Care available for mothers and babies in rural communities.

Standards for infant welfare nursing.

Morbidity and mortality in infancy from measles and pertussis.

Public school education for the prevention of infant mortality.

Vital and Social Statistics.

Dr. S. McC. Hamill, of Philadelphia, is president of the Association, and Dr. Wm. C. Woodward, of Washington, president-elect for 1917. Dr. George C. Ruhland, Health Commissioner, Milwaukee, is chairman of the Committee on Local Arrangements.

The sessions will be under the chairmanship of the following:

Obstetrics—Dr. A. B. Emmons, 2d, Boston.

Propaganda—Dr. George R. Bedinger, Detroit.

Pediatrics—Dr. Borden Veeder, St. Louis.

Governmental Activities and Vital and Social Statistics—Dr. Wm. C. Woodward, Washington.

Public School Education for the Prevention of Infant Mortality—Prof. Abby L. Mariatt, Madison.

Rural Communities and Nursing and Social Work—Dr. Dorothy Reed Mendenhall, Madison.

The session on Pediatrics will be a joint one with the Milwaukee County Medical Society. The session on Governmental Activities will be a joint one with the Committee on Vital and Social Statistics, and the session on Rural Communities will be a joint one with the Committee on Nursing and Social Work.

Programs or other information in regard to the meeting can be secured from the Executive Secretary, 1211 Cathedral Street, Baltimore, Maryland.

MISSOURI VALLEY MEDICAL SOCIETY.—The annual meeting of the Medical Society of the Missouri Valley, under the presidency of Dr. John P. Lord, will be held in Omaha, at the Hotel Fontenelle, on Sept. 21 and 22, and the arrangements are being made by a committee under the auspices of the Omaha-Douglas County Medical Society. Invitations have been sent to a number of men of national prominence, as well as to the presidents of all the State Medical Societies within our province. The program will be limited to twenty papers, thus affording more time for discussion. A cordial invitation is extended to the physicians of nearby states.—CHARLES WOOD FASSETT, Secretary.

## APPOINTMENT.

DR. FRANKLIN C. McLEAN, of the Rockefeller Institute, has been appointed professor of internal medicine at the Union Medical College, Peking, China.

## RECENT DEATHS.

DR. JAMES H. WHEELER, 71, of 124 North Street, one of the oldest physicians in the city, died last week, on July 25, in Pittsfield, after a brief illness. Dr. Wheeler was born in Lowville, N. Y., coming to Pittsfield shortly after graduation from the Detroit Homeopathic Medical College in 1873. He leaves two sons, Dr. Ralph D. Wheeler of Pittsfield, and Dr. Roy M. Wheeler of Springfield, one brother, John Wheeler of Pueblo, Col., and a sister, Mrs. Jane Reese of Watertown, N. Y.

DR. ROWLAND COX, JR., of 287 Broadway, Paterson, N. J., who was for seven years instructor in operative surgery in the College of Physicians and Surgeons, New York, died on Aug. 2 in the New York Hospital, in his forty-fifth year. He was connected with the Paterson General Hospital and was a member of the City, County and State Medical Societies of New York. He leaves his son, mother and two brothers.

#### CONTACT POINTS BETWEEN PULMONARY TUBERCULOSIS AND SYPHILIS.

BY JAMES A. LYON, M.D., RUTLAND, MASS.

IN searching through the voluminous literature on the subject of pulmonary syphilis, one is amazed and bewildered by the diversity of opinions held by the medical profession on this important and, to me in the light of my experience, unusual and uncommon condition. It has been frequently suggested to me that a large percentage of the cases at Rutland would be found to possess definite pulmonary syphilitic lesions, were a careful and diligent search instituted. To test this supposition 471 of our patients have been subjected to the Wassermann test. The results of these tests, together with a study of their clinical significance, form a part of this paper.

The credit for the first anatomical description of pulmonary syphilis must be given to Depaul who, in 1853, read before the Paris Academy a paper entitled "A Manifestation of Congenital Syphilis, Consisting in an Alteration of the Lungs Not Yet Described." Virchow was inclined to express himself with considerable reserve as to

the disease and was doubtful as to most of the cases that had been previously reported. He mentions having observed certain lesions of the lungs which he considered syphilitic, particularly so if there were other manifestations of syphilis elsewhere in the body. The most marked lesions that he found were a fibrous interstitial pneumonia along the bronchi, leading to the formation of fibrous bands passing from the centre of the lung along the bronchi and vessels toward the periphery, thus forming by their contraction more or less deformity of the lung. Along with this condition he believed that in certain cases there was an associated pleurisy, later on forming fibrous nodules beneath the pleura. He states that caseous pneumonia and gummata might also be discovered, and describes cavities formed from the breaking down of foci of caseous pneumonia, thus bringing up the question of syphilitic phthisis. All subsequent descriptions of the disease are based on this work of Virchow.

Carlier, in 1882, collected 75 cases from different sources, and of these he reported the autopsy findings in 50. Hiller, in 1884, collected 87 cases, 84 of which were examined post mortem. Of these Carlier had previously reported 20. Hiller himself reported two cases in which syphilis of the lungs was undoubtedly present, there being also other evidences of syphilis. He is positive in his denial of the existence of syphilitic phthisis and fibrous interstitial pneumonia found in the cases reported by Carlier and Hiller. He considered these lesions as the result of the infection of the lungs by the bacillus of tuberculosis, and considered the description of these lesions as "syphilitic" of "probable" origin.

\* the 84 cases of Hiller with autopsies should be considered as syphilitic, the doubtful cases in all likelihood being pulmonary tuberculosis with fibrosis.

All authorities, with almost the single exception of Paneritius, agree that pulmonary syphilis is rare. Most of the cases that he reported are clinical and consist of rather indefinite pulmonary lesions, with frequently obscure general manifestations of syphilis which responded to iodide of potassium. From the report of the autopsies which he gives it would appear that most of his cases were also ones of tuberculosis.

West maintains that out of 6000 syphilitic patients treated at the hospital in Copenhagen during a period of seven years, only 2 furnished clinical evidence of pulmonary syphilis. He also states that of 18 autopsies of adults who died of acquired syphilis, specific disease of the lungs was found in but three instances. Out of 105 autopsies on children with congenital syphilis the lungs were affected in but four instances. Lenhartz states that his teacher, E. Wagner, could recall but one instance in which he could make a clinical diagnosis of pulmonary syphilis, and in which a cure followed anti-luetic treatment.

Fowler maintains that pulmonary syphilis is a rare disease, and bases his statement on the fact that he was able to find only 12 specimens in the museum of the London hospital of the Royal College of Surgeons. He contends that two of these may be excluded as either not of that nature, or of a character so doubtful that they are inadmissible as evidence. None of these specimens is from a case of congenital syphilis.

Councilman, who reports two cases with autopsy, states that the essential process in the production of a gumma in the lung is a pneumonia with fibrinous exudation, accompanied by a fibrous change in the alveolar wall, the whole subsequently undergoing caseation. A hyaline degeneration of the capillaries of the affected area is stated to be the first step in the process; this is followed by atrophy of the alveolar wall. The alveoli become distended with large pale epithelial cells and fibrin; the cells also undergo hyaline degeneration, forming smooth bodies staining with eosin and varying in size from one-half the diameter of a red blood corpuscle up to that of a large epithelial cell. The capillaries become converted into rigid tubes and their lumen is much narrowed. Similar changes occur in the small veins and arteries. Immediately around the bronchi and arteries there is a formation of connective tissue, and here the alveolar walls show much thickening and contain small round cells. The whole of the structure thus altered tends to undergo necrosis, and when that change is complete a caseous-looking mass results.

Of cases of acquired syphilis of the lungs there are two varieties. In one there are gummata which vary considerably in size and frequency. They may range from one eighth of an

inch to several inches in diameter, and there may be one or several of such masses scattered throughout the lung. In their incipient stage they are elastic and of a whitish or reddish-white color. At a later period they may undergo caseation and soften, or even become of firmer consistency. Accordingly gummata appear so like tuberculous masses that to differentiate them is a difficult problem. They are located in the interstitial connective tissue surrounded by a dense fibrous capsule. It is maintained by some that these gummata may soften and break into a bronchus and thus be discharged, thereby developing a cavity. Osler believes that when such a condition does occur it is caused by the action of tubercle bacilli. Usually these gummata are converted into dry, firm, cheesy masses, or else they undergo transformation into interstitial tissue. In the post-mortem examination of patients dying in the tertiary stage of syphilis stenosis of the small and large bronchi has been found, due to cicatricial contraction. These gummata may undergo fibrous changes, their resulting cicatricial contraction producing stenosis of the bronchi which, if complete, causes atelectasis of the air cells supplied by the stenosed bronchus, while a bronchiectasis may develop on the tracheal side of the stenosis.

The interstitial hyperplasia appears to have no characteristics which would in any way distinguish it from fibrosis due to tuberculosis, except in that it seems to have a tendency to be confined to one lung. This fact has been brought out very clearly by radiographs shown to me a few days ago by Dr. Holmes at the Massachusetts General Hospital. These were proven cases of syphilis, and the diagnosis of syphilis of the lungs was suspected. In one instance there was a marked destructive condition of the whole of the left lung with no apparent involvement of the other, a condition which would not be apt to occur in a given case of pulmonary tuberculosis, because of the improbability of the opposite lung escaping infection. In another case there were two well defined areas, one occupying the upper portion of the left lung, and the other located in its lower portion. These areas were clean cut and the rest of the lung was not affected, nor were there any evident lesions in the right lung. One would hardly expect to find such a condition existing in pulmonary tuberculosis.

The clinical picture produced by syphilitic disease in the lungs is rather indefinite and depends to a great degree upon the extent of the disease process. It is doubtful if a single gumma would produce symptoms unless it should be of sufficient size, or located in such a position as to cause pressure on important blood-vessels, or large bronchi. Likewise, the presence of interstitial changes at the root, or in the interior of the lung, is hardly likely to produce symptoms unless it is sufficiently extensive to interfere with the respiratory capacity.

There is a class of cases, however, in which

the clinical picture of chronic phthisis is observed, and these are described by some authors as pulmonary syphilis. They occur in patients who present evidence of tertiary lues, or have been infected from 5 to 15 or 20 years previously. Whether the symptoms produced in such cases, however, are really due to syphilis is a much-disputed question, and one that has not so far been settled.

It is safe to state that the symptoms referable to pulmonary syphilis are not as a whole alike in every case, nor are they sufficiently characteristic as a group to make positive the diagnosis of syphilitic disease of the lungs, as differentiated from other pulmonary diseases. Indeed there are no symptoms distinctive of pulmonary syphilis.

In regard to syphilitic lesions of the bronchi, it seems of importance to bring out the fact that the signs of bronchitis which are found in the second stage are, as a rule, general in their distribution; while in the tertiary stage they are usually localized, owing to the tendency at that period to form interstitial changes or gummata in the bronchi. If stenosis occurs there may at first be bronchial breathing limited in area, and this may be found most frequently about the root of the lung posteriorly. As the capacity of the bronchi becomes narrowed, the respiratory murmur over the pulmonary area which it supplies becomes more and more altered until finally it disappears when the air ceases to pass the stenosis. If bronchiectasis occurs it will be followed by cough with profuse purulent and often foetid expectoration, and it is also accompanied by general constitutional disturbances, such as loss of weight and elevation of temperature.

Cough seems to be one of the earliest and most prominent symptoms in the cases reported in the literature on the subject. At first it is laryngeal, then it becomes tracheal or bronchial. Dyspnoea would appear to come next in point of frequency, and varies in severity according to the degree of the lesion. It may be mild when the process is slight, or very severe when marked fibrosis or stenosis of one of the main bronchi is present. The dyspnoea tends to become paroxysmal and to assume the character of bronchial asthma. Hemoptysis is not of frequent occurrence, but it may occur and prove fatal. Expectoration may be profuse, purulent, greenish or yellowish in color and offensive. It may also be streaked with blood. Foul expectoration is common in cases of advanced pulmonary syphilis. Pain may be present, but it is not so prominent a feature as in pulmonary tuberculosis. It is usually due to a syphilitic perihepatitis and not to pleural inflammation. Emaciation is not, as a rule, nearly so extreme and rapid as in tuberculosis, but with advanced lesions in the lungs the difference is not so remarkable as to be of any value from a diagnostic point of view. Night sweats may occur. Pyrexia may be present to a greater or less degree, depending upon the extensiveness of the pulmonary lesions. There may be a complete

absence of fever in the early stages of the disease, and on the other hand it may assume the hectic type, as in tuberculosis, if the process is extensive.

The lesions of pulmonary syphilis are rarely of such a nature as to produce physical signs by which they can be distinguished from other pulmonary diseases of an entirely different origin. On inspection there is likely to be an altered appearance of the chest, depending upon the extent and location of the fibrosis, but it will hardly present the retraction of the apices so frequently seen in tuberculosis. If there are extensive changes in the lungs their expansion will be diminished, and there may be unilateral retraction like that seen in cases of fibrosis from other causes. Areas of consolidation and cavities will be recognized by the ordinary signs, probably long before syphilis is suspected.

A careful inquiry should be made into all cases of pulmonary disease as to the possibility of a latent syphilitic infection. It has been my experience in the routine taking of histories that almost invariably a patient will deny that he has ever had lues, and in many instances they are perfectly honest in their statement, because they have not known of the nature of their disease. At Rutland I am able to obtain a definite syphilitic history in many instances only after the patient has been notified of the result of the Wassermann test.

Careful search should be made for syphilitic lesions in the calvarium, the sternum, ribs, testes, larynx, liver and spleen, and if there is a suspicion of syphilis the search should not be abandoned in a case of pulmonary disease with a positive, or even a negative, Wassermann without first having a careful radiograph taken of the lungs and the long bones.

In pulmonary tuberculosis the apices of the lungs are the parts most frequently affected, and the disease has a tendency to spread downward over a definite line of march. One lung is rarely found extensively diseased without an involvement of the other. The lesions of syphilis on the other hand seem to localize themselves about the root, base, and central portions of the lung, and they are, as a rule, confined to one lung, even when there is a marked destruction of tissue. Careful study of undoubted specimens of pulmonary syphilis, however, does not bear out the statement frequently made that the lesions are generally limited to the middle portion of the lung. They are so often found elsewhere that their more frequent occurrence in that part ceases to be a factor in diagnosis.

The presence of cavity signs in the lung and the expectoration of large amounts of serum persistently negative to tubercle bacilli should always suggest pulmonary syphilis. In these cases and in all other doubtful ones a very careful examination should be made by a competent roentgenologist who has had considerable experience in the taking and interpretation of chest films. The Wassermann should also be made, and the

given to every case presenting a pulmonary disease, and a negative finding after repeated tests should not necessarily be considered as evidence to exclude the possibility of a syphilitic origin. In all cases of pulmonary tuberculosis, which are at all doubtful, when the sputum is persistently negative, the subcutaneous administration of Koch's Old Tuberculin should be given in doses and periods laid down for that test. If the tuberculin reaction is negative, and there is a marked Wassermann reaction, and if the x-ray examination of the chest is confirmatory or suggestive, if lesions are found in the bones and there are other manifestations of syphilis present, a diagnosis of pulmonary syphilis would seem probable. On the other hand, if a positive reaction to tuberculin occurs in a given case of pulmonary disease with a marked positive Wassermann, it will be difficult indeed to make a correct diagnosis because the two diseases, pulmonary tuberculosis and syphilis, may co-exist while the x-ray examination may not be of assistance.

It has been suggested by some writers on this subject that if a pulmonary disease which has not responded to ordinary non-specific treatment were put on an anti-luetic treatment, and the process thereupon improved or disappeared, one would be justified in maintaining that the case was syphilitic. It will be noted that in the cases Numbers 1 and 2, here reported, the physical signs in the chest and the general condition showed striking improvement under nothing but the usual sanatorium treatment. Both of these patients had definite signs in the chest, and symptoms pointing to tuberculosis. An x-ray examination made in one of the cases showed an apical lesion. They had a positive and a doubtful Wassermann respectively and negative sputum. On the administration of 1 mgm. of Koch's Old Tuberculin they failed to react, as they did also to 3, 5 and 10 mgms. respectively. Both of these patients were referred to us from large hospitals. They had been examined repeatedly and considered to be tuberculous. During their stay in the sanatorium they have increased greatly in weight, and the physical signs have entirely disappeared. Had these patients been put on anti-luetic treatment and the same result had occurred, we are confident that we should have been disposed to credit the improvement to the therapeutic effect of the drugs. On the other hand, even in a given case of pulmonary syphilis where marked changes in the structure of the lung have taken place, with cavity formation, strictures of the bronchi, etc., one would not expect specific treatment to improve these conditions.

In still another instance (Case 3), where there were marked physical signs in the chest with a negative sputum on repeated examination and a positive Wassermann, the patient was put on specific treatment, mercurial inunctions and potassium iodide, and within a very few weeks the process in his chest became more active. He

began to cough and expectorate large amounts of muco-purulent sputum which contained tubercle bacilli. The x-ray diagnosis in this case was pulmonary tuberculosis, involving the upper two-thirds of the left lung and the apex of the right.

Case 4 had well defined lesions in both lungs. His sputum was positive on admission, but was negative thereafter on repeated examinations. It was only a short time before his discharge that his blood was examined and found to be positive to the Wassermann reaction. This patient gained 26 pounds in weight during his residence, and at the time of his discharge his pulmonary disease was "apparently arrested." The x-ray report is as follows: "Dilated arch with dense mottled areas in both apices." If this patient had been given specific treatment and had made a similar improvement we might have considered that this was an instance of an associated pulmonary tuberculosis and syphilis.

CASE 1. Admitted January, 1916. Female, housewife. Age 28. Married. Family history, negative. Well as a child, with the exception of having had children's diseases. Menses established at 15, but have always been irregular. Was married ten years ago, and has a healthy, living child, aged 9 years. She has had no miscarriages. She gave a negative history to syphilis prior to the positive findings of her Wassermann test, but following this she stated that she had an eruption on her skin shortly following the birth of her child. She had no treatment for this condition. During the past several years she has had pain in her back, suffered occasional chills, gradual loss of strength, anorexia, constipation, and during the past few months has lost about 12 pounds in weight. There has been no cough or expectoration.

In December, 1915, she was treated at one of the hospitals in Boston, and a diagnosis of incipient tuberculosis was made and confirmed by the x-ray examination. The process at that time, so she was told, was in the right apex. Later she was examined at another hospital, and was advised to go to Rutland for treatment. Her application blank was marked "incipient."

On admission she complained of loss of strength, constipation, slight morning expectoration and pain in the back. Her temperature was 99° F. and her pulse was 102.

*Physical Examination.*—Fairly well developed; fairly well nourished; attitude erect; color of lips and mucous membrane normal; teeth in good condition; pupils equal and react. Nares, pharynx and larynx normal. There are several large and small scars about the shoulders and back, which are stated to have been caused by being scalded by hot water. There is no enlargement of the lymph nodes. The chest mobility and symmetry are normal. Heart normal. On percussion there is slight dullness in the right apex anteriorly extending down to the second rib, and posteriorly extending down to the fourth vertebra. Over this area there is bronchovesicular breathing, and there are a few medium râles; the left apex is a little high pitched on percussion, and there are a few fine râles present.

The temperature throughout her stay ranged from 97 to 99° F.; her pulse has varied from 70 to 105, with a steady gain in weight and strength. The

physical signs have gradually disappeared from her chest, and her sputum has been on repeated examinations negative to tubercle bacilli. On March 14, 1916, following the routine examination of patient's blood, she was found to have a positive Wassermann. Consequently, beginning on May 16, 1916, she was given 1, 3, 5 and 10 mgms. respectively of Koch's Old Tuberculin subcutaneously, and there was not the slightest local, focal, or general reaction. This was apparently not a case of pulmonary tuberculosis, and she was discharged with instructions to take specific treatment, having gained 15 pounds in weight.

**CASE 2.** Admitted Feb. 11, 1916. Female. Housewife. Age 25. Married. Mother and father well. An only brother died of pulmonary tuberculosis two years previously. She was delicate as a child, having had pneumonia at the age of three months, diphtheria in childhood, measles, etc. Menses established at 14, irregular. Was married six years ago, and has two children living and well. She had an induced miscarriage two years ago, and has not been well since that time. She gave a negative history to syphilis on admission. During the past two years she has complained of a moderate cough and expectoration, together with pleural pains. She has been suffering from moderate dyspnea, and in May, 1915, she expectorated about a drachm of clear blood. The same thing occurred in January, 1916, but the blood then expectorated amounted to about one ounce. There has been a gradual loss of strength during the past two years. Her usual weight is 110 pounds, but on admission she weighed only 104 pounds.

She had been treated by various physicians, during February, 1916, an application was made for her admission to the State Sanatorium by her physician, who stated that she was between the incipient and moderately advanced stages of her disease. The duration was stated to be two years, and the process was marked as being in the right apex anteriorly.

Her symptoms on admission consisted of moderate cough, moderate loss of strength, insomnia and moderate dyspnea.

**Physical Examination.**—Poorly developed and poorly nourished; attitude erect; color of lips pale; teeth fair; pupils equal and react. Lymph nodes negative. Nares, pharynx and larynx negative. Mobility and symmetry of the chest normal. Heart normal.

There is slight dulness in the right apex anteriorly, extending down to the third rib, and posteriorly extending down to the fourth vertebra; high pitched breath sounds and medium coarse râles are present over all this area.

During her residence her temperature fluctuated between 97.4° F. a.m., and 99.2° F. p.m., and her pulse varied between 70 a.m. and 106 p.m. She gained 10 pounds in weight. Her symptoms have all disappeared, and she is stronger and the physical signs in her chest are now negative.

She had a doubtful Wassermann on two examinations. Her sputum was negative to tubercle bacilli on repeated and careful examinations. On May 16, 1916, she was given 1 mgm. of Koch's Old Tuberculin subcutaneously, which failed to cause a reaction, and consequently she was given 3, 5 and 10 mgms. respectively, following which there was still no reaction. She was therefore discharged as

non-tubercular, with the recommendation that she take specific treatment.

**CASE 3.** Admitted October, 1913. Male. Age 20. Cook. Single. Family history, negative. As a child was delicate, and had the usual diseases of childhood. He denied having had syphilis. His present illness began in March, 1913, at which time he claims to have had a "touch of pneumonia." Since then he has been losing weight, has had a moderate cough and expectoration. He has had a slight evening temperature, night sweats and moderate loss of strength. On admission the foregoing symptoms were still present.

**Physical Examination.**—Fairly well developed and nourished; attitude erect; color of lips and mucous membrane normal; teeth in good condition; pupils equal and react; lymph nodes negative. The ears, nares and pharynx are normal. There is a slight thickening of both vocal cords, with moderate inflammation and catarrh. Mobility and symmetry of thorax normal. Heart normal. There are no scars of any kind upon the body. There is a slight, incipient lesion in the right apex, with dulness in the left lung, extending down to the third rib anteriorly, and to the sixth vertebra posteriorly, in which area there are numerous râles, and also harsh breathing.

During the first few months of his residence he ran a rather irregular temperature and pulse. His sputum was persistently negative to tubercle bacilli. On Aug. 18, 1915, his Wassermann was positive, and on questioning him he admitted that he had had a primary lesion in 1912. He took "pills" for several months, and there were no secondary manifestations of the disease. Iodide of potassium was given, together with injections of mercury. Because of the "two-year residence rule," he was discharged as a patient in September, 1915, as "improved," and took up employment in this institution. Some time later he began to lose weight, his cough increased and he raised large amounts of muco-purulent sputum, which contained tubercle bacilli. The physical signs in his chest increased, and his temperature, which had been normal for several months, became elevated. The x-ray diagnosis was tuberculosis of the upper two-thirds of the left and the apex of the right lung.

**CASE 4.** Admitted June, 1915. Male. Age 37. Printer. Married five years, no children. Family history negative. As a child was well, with the exception of diseases of childhood. He denied having had syphilis. His present illness dated from about one year back, at which time he began to feel run down. In January, 1915, he coughed and expectorated moderately, and later he complained of dyspnea, chills, moderate fever, night sweats, etc. On admission he had practically no cough or expectoration, and none of the above symptoms were present.

**Physical Examination.**—General development fair; well nourished; attitude erect; color of lips and mucous membrane normal; teeth, artificial, good; pupils, lower ones in good condition. Mobility and symmetry of thorax normal. Heart normal. There are interstitial changes in the right lung, involving the upper and middle lobes anteriorly, and the upper lobe and apical portion posteriorly. There are scattered deposits in the apex of the left lung, and of the activity. Whole chest is free from râles.

cally normal temperature and pulse, and his sputum, although it was examined repeatedly, was found to contain tubercle bacilli only once during his residence.

On Oct. 2, 1915, his Wassermann was found positive, and he then informed us that he had had an initial lesion in 1900, for which he took mercurial pills for about one month. In March, 1916, an x-ray examination showed dense mottled areas in both apices. Diagnosis, pulmonary tuberculosis. He was discharged in March, 1916, having gained 26 pounds in weight, and the physical signs in his chest had entirely cleared up, there being nothing present but a few fibroid changes in the tops of both lungs.

Of the 471 cases having received the Wassermann test, 430 were negative, 10 were doubtful, 2 were unsatisfactory, and 29, or 6%, were positive. Of the 430 negative cases 140 had incipient pulmonary tuberculosis, 105 of these had repeated negative sputum, and 35 had positive sputum. Moderately advanced, 222, and of these 75 had negative sputum, and there were 149 instances where it was positive. The remaining 68 were far advanced; and of these 7 were negative, and 61 had positive sputum. The sputum was negative in 4, and positive in 2 of the doubtful cases in the incipient stage; 2 had negative and 2 had positive sputum in the moderately advanced stage. There were no doubtful cases in the far advanced stage of their pulmonary disease. Of the 2 unsatisfactory cases, both of which were in the moderately advanced stage, one had a positive sputum and the other was negative.

A positive Wassermann was obtained in 10 incipient cases, and of these cases 8 had negative sputum and 2 positive sputum. In the moderately advanced stage, 4 had negative and 11 positive sputum. In the far advanced stage there were only 4 that gave a positive Wassermann, and in each instance the sputum was positive.

From my experience at Rutland, and the careful consideration of the cases there, I am firmly convinced that all patients who are suffering from diseases of the lungs should be given repeated Wassermann tests. It is by this method, together with a careful study of the x-ray findings and physical signs in these organs, that we may hope to settle this difficult and complex question of what really constitutes clinical pulmonary syphilis.

#### DISCUSSION.

Dr. W. A. Hinton, Cambridge: I am much pleased with the points Dr. Lyon brought out in his paper, especially the description which he gave of the pathology of the disease. In a review of more than 5,000 autopsies, I do not recall a single case where the diagnosis of syphilis of the lungs was made in an adult. There is a good deal of work to be done on the disease, and we cannot be absolutely certain that lesions

of the lungs which we think are syphilitic are such until spirochetes are found.

In regard to the incidence of syphilis among the tuberculous, out of 1164 cases examined by the State Wassermann Laboratory from patients in the Boston Consumptives' Hospital and in Rutland, 105, or 9%, gave positive reactions; 49, or 4.5%, doubtful reactions. These Wassermann tests were done as a routine in these two institutions. It is of interest to compare these statistics with others. In the case of the Lying-in Hospital, in 1130 cases about 5.9% were positive and an equal per cent. were doubtful. It would seem to indicate that roughly from 5 to 7% of the inhabitants of Massachusetts are syphilitic. I take the statistics of the Boston Lying-in Hospital as giving the average, as these people apply for a specific complaint—pregnancy—and no diseased condition. On the other hand, in general hospitals, about 20% of all patients give a positive Wassermann.

As bearing upon the relative frequency of a negative or positive sputum in the cases with a positive Wassermann test, the following statistics will give some information: In the Boston Consumptives' Hospital and Rutland State Sanatorium in 67 positive Wassermans, 35 had a positive sputum and 32 had a negative. In 707 negative Wassermans, 364 had a positive sputum and 343 had a negative. In other words, there is no more likelihood of finding a positive Wassermann in cases with a negative sputum than in cases with a positive sputum.

In conclusion, I wish to emphasize Dr. Lyon's point to the extent of saying that I believe that all patients, whether private or institutional, who have a diagnosis suggestive of pulmonary involvement, should have a Wassermann test performed.

DR. C. MORTON SMITH, Boston: This subject was first brought to my attention about twelve or fifteen years ago, when a patient of mine, definitely luetic, who had been under treatment for a matter of three or four years, fell overboard down the Harbor one day in June. The wetting and exposure were followed by an attack of pleurisy, according to his description. Two or three months later he applied at one of the hospitals for a chest examination, and was recommended to a State sanatorium as a case of incipient tuberculosis. He remained at the institution about ten months, and during that entire period had a persistently negative sputum. It was before the days of the Wassermann test. The guinea-pig inoculated with his sputum in December was killed the following June, and, at the post mortem, showed no evidence of tuberculosis.

As far as diagnostic signs on physical examination are concerned, it seems impossible to distinguish, from physical examination alone, a case of syphilis of the lung from tuberculosis,

judging from the cases that have proven to be definitely syphilitic; for practically all these cases have either been recommended to, or have spent a certain time in, one of the State sanatoria, having been sent there by experts. It seems to me that the x-ray furnishes one of the most valuable aids in the matter of diagnosis. The distinctions have been brought out by the reader, and I will not dwell on them.

Another point the reader mentioned is the well being of the individual with syphilis of the lung, as compared with the same degree of pulmonary involvement of tuberculosis. It seems to me that, in the matter of syphilis of the lung, the Wassermann is of about the same value as it is in other questions of syphilitic involvement. It is not so much a test as an additional symptom or sign of the disease. When we realize that the Wassermann reaction is positive in a large percentage of cases of leprosy, sleeping sickness, and certain other conditions, we see that it is far from a specific test. There are other temporary conditions in which the reaction is positive, such as certain febrile conditions, malaria at the time of the chill, pneumonia, scarlet fever, and sometimes after ether anesthesia. This winter at the Massachusetts General Hospital there were several cases of broncho-pneumonia that gave a varying degree of positive result, the reaction becoming negative, with no anti-syphilitic treatment, when the fever subsided. Probably other conditions, unknown at the present time, may give a temporary positive reaction.

There is one point not mentioned which I think is of value, and that is the need of performing the Wassermann test on other members of the family—the husband or wife, as the case may be. In cases where the patient fails to give a positive reaction, the mate may give a positive reaction in a fairly definite percentage. The same is true of examination of their children.

The x-ray plates, which Dr. Lyon speaks of as having been shown him by Dr. Holmes, were undoubtedly from one of our cases of congenital syphilis, where one lung is practically consolidated, while the other shows no evidence of involvement.

The persistent negative examination of sputum for tubercle bacilli is another striking point in this condition.

Dr. Hinton has probably given the correct solution of the failure of the pathologist to recognize this condition in the lung macroscopically. In the same way definite specific lesions of long bones are revealed by the x-ray alone.

In the matter of tuberculin tests, Dr. Otis published some cases several years ago where he did the tuberculin test on a certain number of definitely knownluetics, with no signs of tuberculosis. As I remember it, he obtained about 33 1/3% of positive reactions in syphilis. That is interesting in connection with Dr. Lyon's

observations that syphilis fails to give a positive reaction, even in large doses of the old tuberculin. I was interested in what Dr. Lyon said about the tuberculous process lighting up after the administration of mercury and potassium iodide. I was not sure that treatment of this sort would cause irritation or a lighting up of the tuberculous condition, but I am convinced that salvarsan has that effect. I am sure that I have lighted up tuberculous conditions from the injection of salvarsan in patients with a double infection. It seems to me that tuberculosis of the lungs is ordinarily one of the definite contra-indications to salvarsan. The consideration today deals with a definiteluetie condition of the lung, not the combination of syphilis and tuberculosis. A certain number ofluetics are going to become tuberculous, and a certain number of tuberculous individuals will acquire syphilis. These cases of syphilis of the lung that simulate tuberculosis are of particular interest.

I do not wish to enter into controversy with the laboratory men on the subject of Wassermann reactions, but I wish to reiterate once more the fact that the Wassermann reaction is not a specific test for syphilis: it is a group reaction.

All the patients with positive reactions, even though they may be moderate or weakly positive, are sent from the Lying-in Hospital to the Syphilis Department of the Massachusetts General Hospital for observation and treatment. There is a certain number of cases that are reported as "doubtful" or "suspicious." I do not understand that the *reaction* is doubtful or suspicious, but the *laboratory man* is in doubt as to whether that patient should be called *syphilitic* or not. It would seem that more help could be given the physician if the degree of positiveness of the reaction is reported, rather than the report "suspicious" or "doubtful." The moderate and weak positive reactions to the laboratory man mean a definite per cent. hemolytic reaction. When interpreting the Wassermann findings with the clinical signs on physical examination, it may be a resolving syphilitic infection, that gives you only a moderate or weak reaction, or perhaps the patient has been recently under treatment, and thus gives a moderately positive reaction, or it may be one of the *false positives*. It leaves one less in doubt to know the degree of positiveness.

Dr. ROGER I. LEE, Cambridge: The pathology of syphilis and tuberculosis is very similar. We all know how common pulmonary tuberculosis is. On the other hand, our pathologists tell us that syphilis of the lung is very rare. The great difficulty from the clinical point of view comes from the question of diagnosis. We have no means of diagnosing syphilis of the lung in life. We cannot find spirochetes in the sputum. Even if we did they would prob-

ably come from the mouth and not from the lung. We are, therefore, thrown back on the Wassermann reaction, which, as Dr. Smith has pointed out, is, after all, not a specific reaction. The Wassermann test is of tremendous value, and, other things being equal, a positive reaction indicates syphilis. But in the presence of any very marked disease of any sort, one has to be a little chary about accepting a positive and especially a doubtful Wassermann reaction. Furthermore, the presence of a positive Wassermann reaction in no wise necessarily involves the lungs. It is a general reaction and not at all a local reaction in the lungs. We have a positive means of diagnosing tuberculosis of the lungs by finding tubercle bacilli in the sputum. On the other hand, the absence of tubercle bacilli from the sputum, even on repeated examinations, is of no great importance. If the search is persistent enough, we usually find tubercle bacilli. I should be very regretful if this section broke up with the idea that negative sputum examination for tubercle bacilli was of any real value in eliminating tuberculosis, and in suggesting that the disease was syphilis of the lung.

Dr. Lyon and the discussers have rather restricted the discussion to the question of the relation of tuberculosis and syphilis. It seems to me that it is very much wiser to accept the experience of everybody here that, pathologically, syphilis of the lung is very rare, that clinically it is certainly very rare; and to put syphilis down as one of the rare conditions of the lung. One has to admit that there are other rare conditions in the lung which may not be syphilis. Take, for example, pneumonitis, bronchiectasis or actinomycosis, that we occasionally see and cannot explain. In other words, there is a group of pulmonary conditions, usually localized in one lung, which are due to other agents, usually infective agents, than the tubercle bacilli. It seems to me that rather than to say that some chronic non-tubercular condition of the lung, even in the presence of a positive Wassermann reaction, is syphilis, we should say that the condition probably belongs to a rare group of lung infections, and syphilis is simply one of that group.

DR. ABNER POST, Boston: Some years ago I asked one of the gentlemen who had been prominent in anti-tuberculosis work what he knew about syphilis of the lung. He answered me something like this: that he knew there was syphilis of the lung, but did not know that he had ever seen it, and did not know how he should recognize it if he were to see it. We have advanced a little bit further than that. We know that there are certain cases of syphilis of the lung at the present day. We do not know how to distinguish them exactly from tuberculosis.

It is a fact that the advance in our knowledge

of syphilitic phenomena has been due very largely to the clinicians. It was denied for some time that locomotor ataxia could possibly be of syphilitic origin, because its lesions were entirely different from those ordinarily attributed to syphilis, and the clinicians established the connection. I cannot but think that our knowledge of syphilis of the lungs must be acquired in the first place chiefly through clinical study, especially if we may include radiology as a part of the clinical study, rather than through pathology. It seems to me that in cases in which there are symptoms which simulate those of tuberculosis, but in which the lesions in the lungs are unusual, and in which tubercle bacilli are not found, with a positive Wassermann test, we should not make a hasty diagnosis of syphilis; but such cases should be regarded as possibly syphilitic, and from their study we shall learn what the clinical peculiarities are, and shall acquire at length a knowledge of syphilis of the lung which will be worth while.

#### TUBERCULOSIS CARRIERS.

By CHARLES E. PERRY, M.D., NORTHAMPTON, MASS.

IN our campaign against tuberculosis we must consider the individual, the family and the public. Each is of nearly equal importance and their interests so closely allied that it is impossible to consider one without the other.

The individual's rights are to have his disease discovered at the earliest possible time and to have laid before him information concerning the possibilities of an arrest or cure if he follows the proper path, and the probable consequences if he fails to do so. He next should have an early opportunity of admission to a sanatorium, where he may be properly started on his way to health and receive an education that will be useful to him for the remainder of his life.

It is the right of the family to be protected from a source of infection and still not be deprived of the support of the wage earners, housekeepers or the comfort of loved ones for a longer period than is necessary.

The public rights should also be preserved, by protection from sources of infection, as well as by having the funds which the public provides for health work spent judiciously for the purpose for which they are intended.

At first thought, looking at tuberculosis as a communicable disease, it would seem that the problem could be solved by segregating those afflicted, but further reflection shows how obviously impracticable such a procedure would be in a State like Massachusetts, and also brings up the question as to the desirability of such a course.

It is the purpose of this paper to discuss what ought to be our attitude toward probably the

largest proportion of those capable of disseminating the disease—the tuberculosis carriers. By the term carrier, we understand a person who harbors pathogenic organisms, but who himself shows no symptom of the disease.

We have no way of obtaining knowledge of the number of carriers in the State, but there must be many thousands. One of the commissions to investigate tuberculosis in Massachusetts a few years ago stated that tuberculosis is a disease of 40,000 persons, and each one of these probably is, or has been, a carrier some of the time, and it would seem that as our death-rate from tuberculosis decreases the number of carriers will increase. Because of the increasing national or racial immunity we seem to be acquiring, and because of higher standards of living, better housing and working conditions among the poor, and better care of consumptives, with earlier diagnosis and treatment, there will be a lesser tendency for infected persons to advance to the more rapidly progressive forms of the disease, but more of a tendency to establish a resistance which will keep them above the sick line, but still with the disease process active enough to furnish abundant bacilli in the sputum.

The question, then, seems to me to be how dangerous these positive cases really are, who are able to be about and perform more or less work in comparative comfort.

Tuberculosis is a disease in which infection by the specific organism is necessary to cause lesions. There are scientific and clinical reasons to suppose that hereditary and acquired predisposition is an important factor. All persons probably have a certain resistance to the bacilli, which varies from one which is very slight, to an almost, but presumably never absolute, immunity. So in a word, infection depends on the introduction of a sufficient dose of the infecting agent to overcome the amount of immunity possessed by the individual. This resistance depends on a great many factors. Age is an important one,—the older the person the higher the grade of immunity acquired through previous infections, but also to other factors, the nature of which are unknown, but shown by the fact that the older the individual the less liable he is to have acute military tuberculosis, which form the disease takes in susceptible animals and young children without immunity. We also note the fact that phthisis is less common in the aged, and when it occurs, runs a mild, benign course.

It is the opinion of many now that nearly all phthisis is the result of an endogenous infection or an extension from an old quiescent focus acquired in childhood, which is given an opportunity to light up when resistance is lowered, as from other acute infectious diseases, anemia, malnutrition, exposure, undue fatigue, worry, insanity, especially dementia precox, and possibly physical injury. Dr. Knopf in a recent

article quotes at least ten well-known Americans of vast experience as being in accord with this view.

It has been shown by both autopsy findings and the use of tuberculin tests that very few individuals in modern civilized communities reach maturity without having been infected. The percentages vary from 50 to 98, probably differing on account of conditions under which subjects live. It has been shown that new-born infants are free from tuberculosis, and that the number of those infected increases with the age of the child, until at the age of fourteen or fifteen nearly as many are found infected as among adults.

From this it will be seen that nearly all who are infected at all, are infected before they reach the age of fifteen years. This would seem to prove that, in regard to prophylaxis, these children must be the ones to be especially protected, and the younger the child the more important the point, for, as has been shown, the younger the child, the more liable to fatal infection,—in fact children under two years of age seldom survive.

It should be a rule that all positive cases of tuberculosis should be removed from the home where there are children under fourteen years; the only exceptions being, possibly, in a family where there are plenty of funds and a high order of intelligence so there may be complete isolation of the patient, or where, for other reasons, it is more feasible to remove the child.

It may not be well to include all children under fifteen within this radical rule without further explanation. It will readily be admitted that because of the rapid form the disease assumes in children under four or five years of age and because such children have practically no resistance to the infection, absolute prevention of infection is desirable in these younger children. Fishberg states that "75% of children born during the last year of the mother's life, and 90% during the last month, succumb," and that "the exposure of an infant, even in an ideal home, may result in fatal tuberculosis, while life under adverse conditions will not produce tuberculosis unless there is a source, which is usually a human consumptive, and rarely milk derived from tuberculous cows."

It is at this period that there is the greatest danger from undiscovered carriers. Every one in the household wishes to fondle and kiss the baby and every one at times handles its food. Women are the most dangerous, because, as a rule, they are at home all day and have more ample opportunities for infecting food.

Before a child is born a careful examination should be made of every member of the household, and repeated sputum examinations made of all those who are in the least suspected. Particular attention should also be paid to the children, members, as, for instance, the grandparents or others with chronic coughs which pass on

bronchitis or asthma. In these cases the use of the antiformin method for sputum examinations is indicated. It is likely that in this way a great many carriers will be discovered.

All children should be protected from the over-affectionate visitors, who want to hold the baby or kiss or feed it. Children under three years of age should be kept at home and given no opportunities to acquire infection by travel or association with the public in crowded places.

Other children under fifteen, that is, those from three to fifteen years, we see from the study of statistics, are quite liable to infection, but it is usually of a milder sort and tends to affect tissues like bones and glands, in which the process tends to become quiescent; so here, general hygienic conditions and protection from other infectious diseases play an important part in preventing its development later into the phthisis of adults. Agreeing to this, we must not forget that these younger persons are still liable to the severer forms of the disease if the infection is massive enough or the resistance low enough. Such infection takes place only by intimate family association, as is probable in living with an open case of tuberculosis and indulging in kissing, handling of clothing and linen used by such cases, and by the ingestion of food touched by hands infected by tubercle bacilli.

Such intimate contact is not likely outside of the home, and such infection as occasionally occurs in ordinary associations is apt to be mild, and serves only as a means of immunizing the child by relatively harmless glandular tuberculosis. Indeed, this early immunization may be a saving factor in preventing us from becoming, as a race or nation, as susceptible to the rapid forms of tuberculosis as the new-born infant or the primitive races.

As a means to accomplish this separation of children from massive infection, and infants from any infection at all, we need something more than education, and advice by physicians and dispensary nurses. We need laws, and the enforcement of them by competent officials. Some of the money now spent by the public on the care of healthy individuals who may have tubercle bacilli in the sputum, but who have become institutionalized, or too lazy, selfish or unambitious to earn a living for themselves, could be well spent toward this end. Many who have tasted the pleasure (?) of free food and clothing from the board of health, and possibly a comfortable hospital bed during the winter, feel as one did I had the pleasure of knowing. He said "I have tuberculosis, and the public is bound to support me. The heaviest work I ever expect to do is to roll cigarettes." This patient was physically fit for a moderately hard day's work, although his sputum contained abundant bacilli. Such cases, as well as all incorrigible or unteachable consumptives, should be committed to a special hospital suitable for their care.

Now we come to the question of what are the

dangers to adults from carriers of tuberculosis. We have seen that most of us have been infected, and therefore have acquired an immunity which is sufficient for all ordinary use. Those who have never been infected have also a certain amount of resistance, presumably due to maturity of tissues, as well as the immunity which is general to the white race, which will usually carry them safely through life, even though subjected to occasional slight exposures.

That infections of adults may occasionally take place there is to me no doubt, for if the soil is properly prepared, when enormous doses or even frequent small doses are received from without, why should infection not occur, as well as when received from within, from the breaking down of an old process?

Baldwin asserts that "in man no absolute immunity has been observed," but that "the grafting of new exogenous bacilli in the human being in adult life, nevertheless, requires a specially lowered health or enormous doses of bacilli."

The infrequency of conjugal phthisis and of infections occurring in persons of good health who work among consumptives show that adult infections are very unlikely. Statistics of the Brompton Hospital for Consumptives, compiled for periods before and after the discovery of tubercle bacilli, show that this condition is not due to increased care in disposal of sputum.

I can see no fair reason why carriers of tubercle bacilli, in a moderately good state of health, should not be allowed the privilege of almost any occupation not having to do with the handling of food that is not to be subsequently cooked, or those occupations requiring intimate personal service, or in certain dusty trades. Possibly the danger is slight in some instances, but it cannot be so with tuberculous milkers or restaurant waiters. It goes without saying that carriers should not be allowed in occupations that have to do with the care of children, such as teachers and nursemaids. Dusty occupations, particularly those in which metallic or mineral dust is involved, should be forbidden, both on account of the liability of infecting fellow-workmen under conditions which so favorably prepare the lungs for the reception of the bacilli, and on account of the unfavorable effect of dust on the lungs of the carrier himself.

I would conclude, then, from these facts that if we segregate or isolate the advanced and dying consumptives, from whence comes the bulk of infection, eliminate from children under three years of age all chances of contact with open cases or of the ingestion of milk from tuberculous cows, prevent massive infections in older children by avoiding too intimate contact with carriers, and by general hygienic methods, and avoidance of predisposing causes, reduce to a minimum the liability of infection developing into progressive disease, we are on fairly safe ground.

## DISCUSSION.

DR. ARTHUR K. STONE, Boston: Dr. Perry has defined the term "carriers" as "those persons who harbor pathogenic organisms"—in this case the bacilli of tuberculosis—"but who have otherwise shown no symptoms of the disease." To my mind, these carriers form a small and quite distinct group. They are, for the most part, well nourished, and show none of the ear marks of the ordinary tuberculous subject. With the exception that they cough and spit more or less, they have nothing to attract attention to themselves. Usually, it is only accidentally that they are found to be carriers of tuberculosis. Often, after a brief stay in a sanatorium, or possibly simply resting, they are practically well again, excepting that tubercle bacilli continue to be found. These men soon join one of two distinct groups. Either they accept the sanatorium treatment as a pleasure, described by Dr. Perry, or they demand to be free and allowed to work out in the community. Of the two, I believe that the first mentioned is the least dangerous to the community, and it is cheaper to support him in idleness than to have him at large with the chance of infecting several others that must be cared for by the State later on. Let me briefly explain what I mean by this. If the man is simply to be cared for the rest of his life, it should be in some institution where it can be done more cheaply than at the present sanatoria: where at least he shall have something to do in return for his keep. If he wishes to work, I believe in spite of all the difficulties involved to the institution, he should be allowed and encouraged to work at the hospital or sanatorium, in whatever capacity he is capable of serving.

Under certain conditions a man may be permitted to go home and to continue his work. Here the home surroundings, and his ability and willingness to protect others, must be carefully considered before this is allowed to take place. A part of this group belongs to the semi-criminal or alcoholic class,—men with no self-respect and absolutely no respect for the rights of others. This group is a definite menace to everybody and comes into the incorrigible class, for the care of whom something must be done in the near future. This is a very perplexing group to handle. Occasionally, in alcoholic cases, one of these men is committed to jail by a court sentence and then is automatically transferred to the tuberculosis prison camp at West Rutland, where he is held during the time of his sentence. Health officers everywhere should look out for any such person that they know of, and when they are in court inform the court officers of the presence of the tuberculosis, so that this transfer may take place. Some of them really learn something up there, and during their stay, at least, they are where they are no menace to the community at large.

A number of convalescent tuberculosis patients gradually pass into the carrier class, as Dr. Perry has described. Their lungs refuse to heal absolutely. Here I should counsel patience, and then more patience, in the hope that a final arrest will be obtained. If they must work, they should be given employment, so far as possible, in some institution, or under certain conditions: especially careful cases may be allowed to return to their old, or to some especially selected new, occupation. This should be permitted only with great reluctance, especially in those cases where there is any contact with children.

The question has been raised whether these persistent carriers are dangerous where the bacilli have become attenuated, and therefore non-pathogenic. There is nothing to prove that they are not dangerous. Typhoid fever carriers have been found to be persistently and constantly sources of new cases of typhoid. We must all bear in mind the story of Typhoid Mary. Many years ago I made a study of a number of cultures of diphtheria bacilli from a number of persons who had become clinically well of their diphtheria, and found that the diphtheria bacilli were active and very virulent. Dr. Theobald Smith, and Dr. Baldwin, of Saranac Lake, were written to on this subject. They replied that the statement that the bacilli of tuberculosis in carriers are non-virulent is quite unwarranted. Some bacilli, Dr. Smith said, might be considered to be attenuated, or atoxic, but the point could not be determined until cultures had been tested. Dr. Baldwin's reply was along the same line. Therefore, it is not possible to consider any of these carriers as non-infective, but we must consider them dangerous to the community at large.

DR. ADAM S. MacKNIGHT, Fall River: It is very apparent that we must consider this "carrier" subject from different points of view. First, from the standpoint of the physician in charge of an institution; and second, from the standpoint of the physician in every day practice, who has to do with the patient in his home, in his social relationships, with his family. Dr. Perry spoke of the three-fold relationship,—the individual, the family, and the public. It is also apparent that these relationships must be dovetailed in a friendly, helpful way. In other words, the individual with an active tuberculous lesion has certain family ties, and certain duties to perform. There is no reason why tuberculosis should be the cause of upsetting all the relationships of life. In too many cases, when the note of tuberculosis is sounded in a family, it practically means a separation, certain "phobias" come into the minds of the friends and relatives, while the patient, who has his or her own troubles to consider, is set away at an unripe or an unfit time, which, of course, subjects the family to all sorts of discom-

ment, and hardships. The individual, the family, and the public rights, must be considered. At the present time, it seems, we are just "waking up" to the public recognition, that the individual and the family rights must be protected, in the event of separation—due to tuberculosis.

We must not consider the "tuberculosis carrier" in the same class with the "diphtheria" and the "typhoid carrier." The relationship is entirely different. In the case of a tuberculous mother and child, realizing, as we all do, the danger to the child, we must take into account the terrible anguish that comes, when that child is taken away from the mother, or the mother from the child. Take the cases of glandular conditions without any open lesions. In the bone and gland tuberculosis, without any discharge, there is nothing to create the terror of the "carrier" theory.

I should like to differ from Dr. Stone in the way he would handle that "cigarette roller," mentioned in Dr. Perry's paper. I do not think the tuberculous individual of that type deserves any State recognition or, in fact, any recognition whatever, whether he has a positive or a non-positive sputum. I think one of that type should be discharged from a sanatorium, and made to earn his living, and the place he occupied should be given to one of the opposite type—the one who wants to protect himself, his family, and the public. The sooner the public recognizes that condition, and deals in proper manner with the "cigarette roller," the better.

Dr. Perry's definition of a tuberculosis "carrier" is, in my opinion, open to question, and might be somewhat modified.

DR. CHARLES J. DOWNEY, Springfield: In rising to discuss this paper, I feel that we are all indebted to the author for his practical and sane treatment of the subject, and I wish only to emphasize a few points in connection with what he has already said.

Tuberculosis is a body infection. Consumption, phthisis, tuberculosis of the lungs is but the end-result, a final stage of a long-continued semi-pathologic process.

Tuberculosis is an infectious disease, with the infection being nearly always acquired in infancy or early childhood, attacking the lungs in later life, and producing the disease which has been recognized, so long as there has been civilization, as phthisis or consumption.

It is a disease which lasts a lifetime, beginning in infancy and ending in the grave. This being true, infancy and childhood is the field where the battle against tuberculosis must be most vigorously waged.

When we consider that about one-third of the country's population is made up of children under fifteen years of age, and when we consider also that upon the environment of child-

hood depends largely the physical and mental vigor of a nation, we cannot fail to realize the great importance of laying the foundation of an intellectual and vigorous race of people at the earliest date possible.

I agree with Dr. Stone that special hospital accommodations should at this time be speedily provided for the incorrigible and the unteachable cases, who are a menace to the public when at large. We must continue to give the milder adult cases prompt treatment, that the disease may be arrested so that they may return home to the support of their families in the least possible time. But when we touch the children, our duty becomes an all-appealing and a sacred one, and should be grappled with in a courageous manner and with a liberal supply of funds.

Poverty is the great associate of tuberculosis. Men on a laborer's wage increase their families more rapidly than they do their income, and they soon find that they have to feed, clothe and protect a family of six or seven on the same wage that a few years before was used for earning for two or three. The quarters are no larger: there consequently is smaller space for breathing per individual. There is breathing of expired air: the atmosphere is fouled.

The result of all this is diminished power of resistance and a greater susceptibility to disease, especially of the respiratory tract.

We have a problem of education of the families; a problem in home life. If a large percentage of our adult poor have tuberculosis it is mandatory that we all attack the problem in the home, where infection takes place at so early a period in life.

We have worked in the past according to the light we had. As we have become better informed and have had more knowledge on the subject, we must change our viewpoint; we must attack the problem in a new and a better way.

DR. FRANCIS P. MCCARTHY, Brighton, Mass.: In my two years at the Boston Consumptives' Hospital there were about 80 autopsies in tuberculosis. In two years in the Canal Service in Panama, I saw about 200 more autopsies in tuberculosis. In the past ten years there have been about 5000 autopsies done on a large number of cases, including over 1000 cases of advanced syphilis. There were no cases of pulmonary syphilis in this group of cases. The question comes up today as to whether the pathologist is overlooking syphilis of the lung. I do not think he is. Routine examinations frequently are made to find spirochetes in questionable lung nodules or in the walls of the bronchi. None have been found in these cases in question. The finding of treponema in the aorta and brain would indicate that we ought also to find these organisms in lung processes of syphilitic origin. The problem seems to be purely patho-

logical. Until the pathologist reports increasing numbers of cases of syphilis of the lungs, the disease is still rare. If we discover in the future more cases of lung syphilis, as a result of pathological and bacteriological examination, then the disease is becoming more common. Last year at this meeting there were cases reported where patients in the active secondary stage of syphilis had signs in the chest which might simulate tuberculosis, even to the expectation of a certain amount of blood. This process in the chest is probably a bronchitis, with engorgement of capillary vessels of the bronchial mucosa, with rupture of these vessels, and of a transient nature, occurring in the secondary stage of the disease.

Dr. Hinton brought out the point that the finding of positive sputum and negative sputum in relation to the Wassermann test, is very important. In the positive Wassermann cases the sputum is not any more often found negative than in the negative Wassermann cases. I still think that the disease, as Dr. Lee has brought out, is rare, and is not becoming more common, and until the disease is recognized at the post-mortem, the clinician must keep the diagnosis of syphilis of the lung in abeyance.

Dr. E. O. Otis, Boston: I would like to emphasize Dr. Perry's very conservative and, in my opinion, just statement, that carriers who are able should not be prevented from engaging in any occupation, with the exception of such a one as would bring them into intimate contact with children. We talk very glibly about the isolation of the consumptive, and in certain cases this is the only obvious thing to do, as with the incorrigible consumptive. There are a large number of the active tuberculous individuals, however, whom we shall never be able to isolate, and it would be an unwarranted infringement upon their liberty if we could do so, for according to our Declaration of Independence, all men have the "inalienable right to life, liberty and the pursuit of happiness." However, the consumptive in his "pursuit of happiness" must not jeopardize the happiness of another. All we are warranted in doing is to educate the consumptive who is about among people so that he will not be a menace to others.

In our campaign against tuberculosis we have so alarmed the public that the poor consumptive is not infrequently made to suffer unreasonable hardship. I recall the case of an active tuberculous person of comfortable means for whom I tried to find a home. After vainly trying several private hospitals, she finally found a place in a hotel. Again, a single gentleman with advanced, active tuberculosis, and yet able to attend to his business, told me that he was living at one of the hotels in the city, as he considered that in this way he could best conceal the fact of his disease. As there was generally a new person in the adjacent rooms every night,

his paroxysms of coughing were not complained of. It seems to me that we have got to accept whatever risk there may be in the tuberculosis carriers who are about, just as we take many other risks in life. We cannot isolate all active tuberculous cases or carriers. All we can do is to see that they are properly instructed as to the protection of others from their infection, and trust to their conscientious observance of the rules of prevention.

Dr. CLEVELAND FLOYD, Boston: This term "carrier" was originally applied to convalescent typhoid fever patients who were free from clinical symptoms and signs of the disease, but there was a carrying about of the organisms which could produce the disease in others. The word "carriers," as applied to tuberculosis, should be restricted to a very limited number of patients who are without signs and practically free from symptoms. There are such cases in all large clinics. Such a person will come in because urged to do so, having a little clearing of the throat in the morning, but no clinical signs or symptoms. These patients occasionally show tubercle bacilli in the throat clearings. I have seen two or three yearly whom I should say would come under this head, where repeated chest examinations, not with x-ray, but with ordinary clinical examination, showed nothing in the chest. We should limit the term "carriers" to this type of infection.

The question then arises as to how dangerous patients clinically discharging tubercle bacilli are to the general public. Some time ago I took a series of fifteen cases, collected their sputum, isolated the organism, grew it out on media, and injected the living organisms into a series of guinea pigs to see what I could find out as to the variation in the virulence of the organisms. Some of these cases were in the second, some in the third stage; some had run but one year, some five or six years, but were still throwing off bacilli. In all these fifteen cases there was a variation in the length of time the disease had run. The more chronic the disease, the longer the animal lived, but in every instance the animal succumbed. This may give us some idea as to whether we should allow these people to be at large in the community. At the Mattapan Hospital today there are a number of men who have been there from one to five years. I do not believe that the person who is throwing off tubercle bacilli, and who is ignorant and careless, should be allowed at large in the community. I think the place for that man is in a hospital, even if it is necessary to keep him there under compulsion. I do not mean to include in that group the man who is well trained and educated. We must expect that he would naturally consider other people, but sometimes, even among the most carefully trained and educated, there is often a lack of care.

If this is true among the trained, what can we expect from the ignorant and indifferent consumptive? Such cases should be isolated as long as they are a menace. In this way alone can we hope finally to check this disease.

### WHAT CONSTITUTES CLINICAL TUBERCULOSIS IN ADULTS?

By GEORGE L. SCHAPT, M.D., SPRINGFIELD, MASS.

THE correct answer to the question as asked in the title of my paper this afternoon would be as welcome probably as would the correct answer to the question of a decade ago, "How old is Ann," and I, for one, feel that it would be just as welcome. Any discussion that has to do with the necessary factors, such as history, constitutional symptoms, physical signs, considered requisite for a correct diagnosis of clinical tuberculosis in the adult, is of necessity more or less a compilation of the ideas and experiences of other men working along similar lines, and to some extent the conclusions reached from the observation and study of many cases by the individual.

I trust that I shall not appear dogmatic in my remarks and the conclusions reached, but it would seem that dogmatism on the part of many of us is more or less necessary in arriving at general conclusions as to the values to be placed upon the different factors necessary to the making of a positive diagnosis of active pulmonary tuberculosis in the adult. If it were possible for us to make definite answer to such an important question, one so far-reaching in its effects and results, economically and otherwise, we would be far along toward ultimate victory in the campaign against tuberculosis; it would make the work, of not only the general practitioner, but of the expert as well, much easier. This question, however, cannot be answered by the setting aside of one or two constitutional symptoms and one or two physical signs, and saying that these together in every case make up the symptom-complex necessary for the diagnosis of clinical tuberculosis. Smith<sup>1</sup> well says: "There is no easily applied test for clinical tuberculosis. A negative physical examination is not conclusive, and a prolonged observation of the general health is often necessary." Pottenger<sup>2</sup> says: "That in studying the clinical history and the symptom-complex of pulmonary tuberculosis, everyone must have been more or less impressed with the indefiniteness of the symptoms and signs connected with this disease. There are some 25 or 30 different symptoms which accompany early tuberculosis, and even more in advanced tuberculosis; and, if we think of each symptom as an individual entity, there is no end of confusion." He also says: "It is characteristic of the symptoms of early tuberculosis that they are inconstant.

We do not find any single symptom or any particular group of symptoms present under all circumstances."

We can no more say that a slightly increased pulse rate with a little temperature elevation means active tuberculosis than can the general practitioner say that a dirotic pulse and a positive Widal in every case mean typhoid fever. For in either case we may have other conditions simulating tuberculosis on the one hand, and typhoid on the other, from which it is very difficult to separate the true from the false.

Personally, it does not seem to me that consideration of this question limits us to the consideration of what constitutes the diagnosis of so-called incipient tuberculosis only, but that rather, we should take a broader view of the question and consider this afternoon what we need in each individual case to make a positive diagnosis in the patient presenting with symptoms simulating either early tuberculosis, moderately advanced tuberculosis or far advanced tuberculosis. Evans<sup>3</sup> some time ago called attention to the fallacy of using the term "incipient tuberculosis" in describing a condition, the pathology of which was sufficiently advanced to give rise to demonstrable physical signs, and that true incipency in lung tuberculosis is not clinically demonstrable. I believe that as many errors in diagnosis are made in those adults seeking us for advice with symptoms which they or their medical adviser construe to mean tuberculosis not alone in the early stages, but in the later stages, and I feel that many of you will agree with me when I say that, looking back, we can recall that in many a patient who presenting with fever, increased pulse, cough, and perhaps a râle, it was with the greatest difficulty we were able to arrive at any definite conclusions, if we arrived at any. I feel no hesitancy in saying that, for my part, the diagnosis in these people has caused me as much concern as any with whom I have been confronted.

It would seem that we have clouded the diagnostic field in the last few years by focusing our attention simply upon the question, is or is not this a case of beginning pulmonary tuberculosis, and losing sight of the many that come asking the question, have I or have I not active clinical tuberculosis, and bringing definite symptoms of some pathological condition existing in the pulmonary tract, not necessarily tubercular, but demanding just as sincerely a diagnosis, and in so demanding calling upon the highest degree of medical equipment and scientific accuracy for making the correct one. I cannot but feel that it is here that most errors in diagnosis are made, notwithstanding the widespread feeling that seems to prevail among the medical profession, that it is a simple matter to make a diagnosis of tuberculosis in the moderately advanced or far-advanced stages.

Minor<sup>4</sup> of Asheville, in discussing a paper at

the recent National Tuberculosis Association Meeting in Washington, said, that in his opinion, it was the inadequacy of ability to listen and to interpret signs and symptoms in making an early diagnosis of tuberculosis that accounted for so many errors. He also emphasized the fact that most general men look for loud moist râles before making a diagnosis of incipient pulmonary tuberculosis, but that it was his opinion that when these were heard the case was advanced beyond the incipient stage. I would again emphasize it as my opinion that it is the inadequacy of ability to listen and to interpret signs in the making of a diagnosis in the advanced stages also that accounts for the presence in the many sanatoria of the non-tuberculous cases and those coming to autopsy.

During the last year<sup>5</sup> 1629 patients were admitted to the four sanatoria of this State; of this number 12 were non-tubercular and 16 not determined or classified. I do not quite understand the meaning of the term "not determined," unless it means that these cases were sent in without diagnosis or had not been examined before the report was made up. However, we have here 28 patients out of 1629 who either did not have tuberculosis or in whom it was questionable—a matter of 1.6%. Ash,<sup>6</sup> in a careful study of the pathology of the mistaken diagnoses at the Boston Consumptives' Hospital analyzed 198 necropsies performed in that institution since its foundation; 23, or 11.5%, proved to be non-tuberculous, in so far, at least, that there was no active lesion demonstrable. The anatomic diagnoses were:

	No.	Percentage of Non-tuberculous.	Percentage of Total.
Pneumonic sequelae	8	34.5	4
Chronic cardio-renal	5	30.5	3.5
Aneurysm of aorta	2		
Malignancy	5	21.5	2.5
Septicæmia	2		
Actinomycosis	1	13.5	1.5
		100	11.5

He also collected 353 necropsies performed at other institutions, and of this number 38, or 10.8%, proved to be non-tuberculous, showing, as he says, that the experience is not a local one, confined only to this institution. Anatomic diagnoses of these cases were:

	No.	Percentage of Non-tuberculous Necropsies.	Percentage of Total Necropsies.
Pneumonic sequelae	3	8.0	0.8
Cardio-renal	22	58.5	6.2
Aortic aneurysm	4	10.5	1.1
Malignancy	2	5.0	0.6
Septicæmia	2	5.0	0.6
Syphilis	4	10.5	1.1
Pellagra	1	2.5	0.3

In his conclusions Ash says, "It may seem radical to be sounding a warning against diagnosing tuberculosis, but it must be remembered that we are dealing here with types of cases

that are confused with those in the advanced stages of tuberculosis, in which it is very unlikely to be overlooked; and that we are not considering the early stages of the disease, in which the tendency is to err in the other direction, that is, fail to recognize the presence of the infection." Hawes<sup>7</sup> mentions many conditions that were wrongfully considered to be tuberculosis, among them chronic influenza, hypernephroma of the lungs, chronic empyema, syphilis and abscess of the lung. Luetscher,<sup>8</sup> in an interesting study of respiratory infections, asserts that 62.5% of all non-tuberculous infections below the larynx are due to pneumococcus and 28.5% to the influenza bacillus, and that these organisms together cause 91% of the infections of the bronchi and lungs, 75% of the infections of the larynx, and 31% of the infections of the nose, throat and sinuses.

From a consideration of these figures, it would seem that there are certainly enough errors in the diagnosis, not only of the early case, but of the old case as well, to cause us to pause and carefully to consider and correlate the physical signs and constitutional symptoms of each individual case and not make a diagnosis upon one or two symptoms that may indicate that the individual is suffering from some vague infection in the pulmonary tract, and not, of necessity, infection with the tubercle bacillus. Blue-mel,<sup>9</sup> among a large number of soldiers sent to him with the diagnosis of pulmonary tuberculosis, found that 80% did not have the disease. The symptoms and signs which had led others to the diagnosis were cough, pain in the chest, expectoration, and slight evidence of the impairment of resonance over the right apex, with some changes in the breath sounds. When we stop to consider the enormous number of individuals being sent yearly to the different State sanatoria, not only in Massachusetts, but in every State in the Union, and when we consider the numbers sent who are not tubercular, it should cause us to speculate upon the adequacy of our individual ability to interpret the signs and symptoms of this infection and to endeavor to formulate in our own minds a symptom-complex or symptom-complexes that will permit us to say with more accuracy than we have in the past that this man is tubercular or that this man is not tubercular.

I would not wish you to feel from the foregoing remarks and from any I may make later that it is my desire to belittle the efforts of the general practitioner or expert in the diagnosis, but I do wish to express the opinion that we must use more care in correlating the evidence leading us to label any one as tubercular. It is Fishberg's<sup>10</sup> opinion that from the social and economic standpoint a diagnosis of tuberculosis is a serious affair and that we should not hurry in making it. "There are some of our ground," it is argued, "tuberculous, to be cured, must be taken hold of in time, and that

there is comparatively little harm done if a few persons are inconvenienced, provided the vast majority of tuberculous persons are discovered in time. This would be important if true, but it is not. That all tuberculous patients could be cured if discovered in the incipency of the disease is one of the numerous traditional errors which abound in practical medicine and the sooner we are rid of this error the better for the patients and for the physicians.

It is my firm conviction that as many, if not more, individuals are every year labeled with the diagnosis of pulmonary tuberculosis on just as insufficient grounds as are sent away from our offices with the diagnosis of non-tuberculosis after insufficient examination and consideration. I am certain that many will agree with this statement, when it is recalled how many lesions of the pulmonary tract may simulate in every detail pulmonary tuberculosis presenting varying symptoms from hemoptysis, rapid pulse, temperature, and cough to extreme emaciation and death. Agreeing with Fishberg,<sup>10</sup> it has been a question in my own mind whether the feeling so prevalent is correct, that it is better to be mistaken in making a positive diagnosis on one innocent person, than to err in not making a diagnosis on a tubercular. More and more I am convinced that this feeling is not right and just, and that if we would but use more care in our examinations, with a better understanding of the symptomatology and physical signs, availing ourselves of the scientific methods of diagnosis at our disposal, we would be able to say more definitely in practically every case whether the disease exists clinically and is active.

I trust that I shall not be misunderstood in my remarks and have you think that I desire to belittle the work and endeavors of those who strive for the earliest possible diagnosis of this disease, for I appreciate as much as any one the extreme value of early diagnosis. It is rather my belief, however, that in seeking the early diagnosis and the late diagnosis also, that we should endeavor by all means at our hands to make it correct as well, remembering that there are other pathological entities, which may resemble tuberculosis in every respect, within the thorax.

I wish next to consider the question of the values that shall be given the different signs and symptoms due to pulmonary infection which we consider necessary in enabling us to say definitely that active tuberculosis is or is not existent in the lung tissue. In this discussion, we run the scale from the time of Hippocrates and Galen, who wrote so much on the so-called "habitus phthisicus," and who placed so much dependence upon the presence of this so-called phthisical chest in the making of a diagnosis, to the so-called modern practitioner, who still insists and demands a positive sputum

with the presence of bacilli before he makes a diagnosis of beginning tuberculosis. We are all of us more or less prone, I believe, to have ideas as to the values of the different signs and symptoms required before we individually will make a diagnosis. I think that in many clinics, that in many private offices as well, a patient presenting for examination and diagnosis is too often approached by the examiner with his mind prejudiced by certain symptoms, such as cough, night sweats, etc., more or less made up as to what he should and what he must find to tally with them in the examination of the chest, considering every patient as tubercular until proven otherwise.

As one is confronted with the numerous articles bearing upon the subject of the diagnosis of tuberculosis, it is truly amazing to note the differences apparently existing in the minds of the writers as to the requisite signs and symptoms which they deem necessary and demand before making the diagnosis. Some years ago, it was whispered abroad that a well-known phthisiologist claimed that it was possible and that he would himself make a diagnosis of clinical tuberculosis on a rapid pulse, from 90 to 100, maintained during rest, and in the absence of any other constitutional symptom or physical sign. From this tyro, and the general practitioners and experts who insist—and perhaps they are right—that every case of hemoptysis is tubercular in origin, to the general practitioner who still insists upon the absolute necessity of positive bacillary findings in the sputum before labelling the patient as tubercular, it is a long road. We have, also, those men among us who, overcome by the brilliancy of the radiogram, hypnotized by the brilliant diagnostic skill and verbal acumen of the roentgenologist will permit a diagnosis of active clinical tuberculosis to be made on the radiogram alone, in the absolute absence of any signs or symptoms, permitting the patient to be sent away on these slender grounds.

It has been a source of much interesting study during the past few years to observe the varying symptom-complexes which different competent men of my acquaintance have insisted be present before they would make a diagnosis, and in many cases making a wrong diagnosis because of the presence of some symptom or sign, or both, considered by them as always belonging to pulmonary tuberculosis and to no other condition. The number of men who still insist on cough, dulness, râles, and in some cases positive sputum before making a definite answer, is astonishing. The same may be said of the number who, in the presence of cough, dulness, râles and other signs of an apparent moderately advanced or far advanced case of tuberculosis, but without any symptoms whatever, invariably make an immediate diagnosis of tuberculosis, without proper or careful analysis of the condition in all its phases.

I was much interested while in Washington last month, in ascertaining from some of the men present, the signs and symptoms, and the values they gave them, upon which they would make a clinical diagnosis of tuberculosis in the adults. It was very interesting to see the way in which different signs and symptoms were valued. For instance, how much dependence one man placed upon some factors, such as temperature and pulse, and again how little another man placed upon the same. I wish only to cite the opinions as given me by two or three men present. One gentleman of long sanatorium experience said that he insisted upon the presence of a localized râle or râles in the lung at or near the apex before making a diagnosis of clinical tuberculosis in the adult, notwithstanding the constitutional symptoms presented. Another gentleman placed a great deal of stress upon the history, particularly of contagion, and upon the constitutional symptoms demanding an afternoon temperature of 99.5 and a pulse between 90 and 100. He did not, however, insist upon the presence of the râle. The third man also placed much dependence upon the history, and said that in his opinion dyspnea was always one of the early symptoms of clinical tuberculosis. That dyspnea with an increased pulse rate and afternoon temperature with cough were the four symptoms upon which he placed the greatest reliance.

From the consideration of only these three differing opinions, I believe it can be realized how difficult it is to arrive at a conclusion as to the ideal symptom-complex in the making of our diagnosis. It seems that the value of the different constitutional symptoms and signs following infection produced by the tubercle must always remain more or less individual, and that there must always be a question of personal equation and the varying abilities of the men, as Minor, quoted above, has said, in interpreting signs and symptoms. I do not believe anyone, no matter how experienced or expert, can say dogmatically that this or that symptom-complex means tuberculosis in every given case, but that it is rather a judging of the values of the symptoms and signs, individually and collectively present in each patient, that will aid us.

I feel that between the varying demands here represented, we have, on the one hand, those who make their diagnosis on a foundation too slight and, on the other hand, those that demand too much; and in my opinion one is as bad as the other. Both are irrational in their methods of diagnosis and show the need for more serious study in each individual case and better correlation of the history, physical signs, and constitutional symptoms. It would seem that for some time the diagnosis of clinical pulmonary tuberculosis has been regarded as a very easy problem and that the responsibility resting upon the physician for labelling a man or

woman as a tubercular is *nil* and not to be considered of any importance. I do not agree with this attitude and feel that we should withhold our diagnoses until we are convinced in our own minds that tuberculosis is present.

As intimated before in this paper, I believe it is impossible for any one man to say that any one particular group of symptoms or signs would always mean tuberculosis in the adult. From my experience, I am convinced that a patient may present with varying symptom-complexes of all sorts and types of symptoms and signs and yet upon many of them we will be unable to make our diagnosis. I feel certain that many will agree with me in this contention. It is not my purpose in this paper, in considering the signs and symptoms necessary for a diagnosis of clinical tuberculosis in the adult, to go into the anatomical explanation and the pathological conditions that make for each sign and symptom. I do not feel that I should take your time in doing so, nor do I feel it necessary to go into the consideration of every possible sign and symptom which a person with some pathological condition existing in the pulmonary tissue and adnexa simulating tuberculosis may have, since many of them are of very little value at best. It is my purpose rather to take up some of the signs and symptoms which in conjunction with other signs and symptoms convey to our mentality definite conclusions.

Heise<sup>11</sup> of Saranac Lake, in discussing a paper on the early diagnosis of pulmonary tuberculosis at the recent National Association Meeting in Washington, brought out a number of very interesting points which I think would be of interest here and would perhaps make clear in the minds of many why two or three persons of the same apparent amount of infection react so differently. He emphasized the fact that we must always bear in mind that there are two types or classes of tubercular infection of the pulmonary tract, one the peribronchial type, and the other the parenchymatous type. He again emphasized the fact that in both, the constitutional symptoms of fever, rapid pulse, cough, etc., are present in equal degree, and also that the physical signs were the same in many of the cases. The important point to my mind that he brought out, however, was that in only 3% of the peribronchial type of infection were tubercle bacilli found in the sputum while 17% of the parenchymatous type of infection showed them present, also that the percentage of relapses in the peribronchial were only about one-half, or 50%, of the relapses occurring in the parenchymatous type. A reconsideration of the cases that many of us have seen with these remarks in mind, will, I am sure, clear up the reasons why we never found the tubercle bacilli in the sputum in some of our relapses were so frequent in others.

Pottenger, in a very interesting article of recent date has suggested that these relapses of

early clinical tuberculosis be classified according to their etiology, grouping them into three groups: those caused by the toxins, those of reflex origin, and those due to the tuberculous process *per se*. As he remarks, some have a double etiology and will be found in more than one group as will be seen by referring to the table below:

TUBERCLE TOXINS.	REFLEX ACTION.	TUBERCULOUS INVOLVEMENT PER SE.
Malaise.	Hoarseness.	
Feeling of being run down.	Indigestion or loss of weight.	Frequent and protracted colds.
Lack of endurance.	Chest pains, particularly aching	Spitting of blood.
Nervous instability.	of the shoulders and over the	Sputum.
Indigestion or loss of weight.	apices and upper portion of	Pleurisy.
Night sweats.	lung.	Temperature.
Temperature.	Tickling in the larynx.	
	Cough.	
	Increased pulse rate.	
	Flushing of face.	

A study of these three groups will reveal that we have here every possible symptom that might be expected to occur following pulmonary infection with the tubercle bacilli or other infecting organisms, and also other infecting and pathological conditions outside the pulmonary tract. I think it well to bear in mind that any one of these symptoms or many of them may be caused by conditions outside the thorax. As Hawes<sup>13</sup> well says, "Failure to bear in mind that it is perfectly possible for a person to lose weight and strength, become weak and even develop a cough and run a fever without this being due to tuberculosis, is to be kept in mind. In these days, when the professional and lay mind is constantly being prodded in regard to tuberculosis and its cure and prevention, it often happens that the young and enthusiastic medical student or physician becomes imbued with the idea that tuberculosis is the cause of all our chronic coughs, colds, and run-down conditions. To a large extent this is undoubtedly true, but the fact that there are many other causes of such conditions must not be forgotten."

I am certain that none of us would care to take the responsibility of making a definite diagnosis, breaking up a home and sending a patient away on one or two of these symptoms alone, but would rather require a number of them and other factors before making up our minds. It is not possible, in my opinion, to classify the physical signs due to invasion of the lung tissue in a manner such as this, in view of the fact that so many pathological conditions may cause signs exactly similar to those produced by the tubercle bacilli from the r  le, consolidation, transmitted voice to bronchophony, pectoriloquy and signs of cavitation.

I have become more and more convinced in the last few years of the value of the history in the making of a diagnosis. I do not contend, as do some, that it is possible to make a definite diagnosis on the history of tubercular exposure, not alone in the family but from a room mate, shop mate, a school companion or what not, but

it is certainly of the greatest possible aid to us. Hawes<sup>13</sup> puts the matter in a nutshell when he says, "There is probably no disease whose onset is so insidious as tuberculosis, unless it be some forms of gastric cancer. There certainly is no condition in which a detailed and painstaking history is of more real value in diagnosis, as well as in future treatment." Many other com-

petent observers have in recent articles repeatedly emphasized the value that consideration of the history gives in the making of a diagnosis. It would seem, however, that many general practitioners ignore the question of the history completely, contenting themselves with a little percussion and a little auscultation of the chest, basing their opinion upon those factors alone. I do not think the value of the history in making a diagnosis, not only in the so-called incipient or early stage of tuberculosis, but also in the moderately advanced stages can be emphasized too much, or brought to our attention too frequently.

Let us now consider the constitutional signs and their values. I feel that Pottenger has, indeed, made it very easy for us in his explanation of the signs from the etiological standpoint, as just mentioned. He says that signs due to the toxin itself are not indicative always of an infection due to the tubercle bacilli, but may be caused by any infection that depletes the organism. Surely malaise and the feeling of being run-down are always prevalent. Instability can never be considered as a symptom in any way of infection with but one bacillus, nor can night sweats nor temperature. Any and all of these symptoms may be experienced by persons suffering with almost any low-grade infection. Without a definite history of tubercular contagion, I feel that most of these symptoms are of little value; with a history, of the greatest value.

*Indigestion or Loss of Weight.* How frequently we see patients who come complaining of a little anorexia, a little indigestion or a little loss in weight. There is certainly much misunderstanding about the normal weight in a given individual, and, as a matter of fact, I think that the average man knows as little about his normal weight at any time as he does about anything. This symptom itself is of little value unless accompanied by several other symptoms.

*Temperature Curve.* In the early diagnosis of tuberculosis, the temperature curve is of

great value, and particularly so if other suspicious symptoms are present along with it. In the consideration of this symptom, a few remarks regarding the necessary care and exactness required do not seem out of place. It would seem that too many men are content to take a morning and an evening temperature, specifying neither time at which it shall be taken nor how long the thermometer shall be kept in the mouth. It is my opinion that the ordinary temperature chart kept in this way is valueless. It teaches us nothing. The ideal temperature chart in the suspicious case should be taken every two hours, or if this is not possible, the first temperature should be taken on awakening, again at 12 M., again in the afternoon about 4 or 5, and again about 8 P.M. The temperature chart kept for two or three days is of little value, but should rather be kept at least a week as outlined. It perhaps seems unnecessary to remark that the patient should not take the temperature after having had hot or cold drinks in the mouth; but how often we see just this thing done, and naturally the chart loses its effectiveness.

**Night Sweats.** Night sweats may be due to the action of any particular toxin on the vasomotor system, causing lack of tone and undue relaxation,—a symptom in my opinion the value of which is somewhat exaggerated, and one upon which I do not think it possible to make a definite diagnosis of tuberculosis alone.

Let us next consider the symptoms due to the reflex action of the tubercle toxin. These, as a consideration of the chart will show, vary from hoarseness, chest pains, tickling in the larynx, cough, etc.

**Hoarseness and Chest Pains.** Hoarseness is often found as one symptom of early tuberculosis. We all appreciate how common it is in the advanced stages, when necrosis is present and cavity formation has taken place. I feel that we should pay more attention to the aching over the shoulders and over the apices of the upper portion of the lungs and the chest pains, for it is remarkable the number of patients who complain of these pains and aches early in the infection.

**Cough.** The cough, which is probably the first symptom appreciated by the patient, above all others, and the one which brings him to his family physician or the specialist, is not necessarily due to the tuberculosis of the lung, and we should not prejudice our minds with that fact. That it is difficult for the laity with very little elementary knowledge of medicine, not to be impressed with this symptom, is not surprising, and I think it is the one symptom that always means pulmonary tuberculosis to them. This condition should not obtain among trained medical men, but that it does we must admit, and that there are medical men who still are impressed greatly by this symptom is a fact. I do not exaggerate when I say that the word cough

and the symptom itself convey to the minds of us but one pathological entity—tuberculosis. It is regrettable and I believe the reason for more errors in diagnosis than any other one symptom.

**Increased Pulse Rate.** This particular symptom, and again I would emphasize that it is not a pathognomonic symptom of tuberculosis infection in any sense, since the toxin action of any infecting organism causes an increase in the pulse rate, and one of the symptoms we expect and look for. As yet, I am not prepared to accept the pulse, in the absence of other symptoms or signs, as an indication of tubercular infection.

These reflex symptoms are not in any way distinctive, yet they are much more so than symptoms due to toxins themselves, and if accompanied with other symptoms, should arouse suspicion regarding possible infection of the pulmonary tract with tubercle bacilli.

Pottenger,<sup>2</sup> speaking of these groups, says that there is nothing distinctive of tuberculosis in that group which is due to toxemia, and that he was further impressed with the fact that the second group, those of reflex origin, all point to organs other than the lung, but that they belong to organs which are supplied by the vagus and sympathetic nervous systems, both of which supply the lung.

**Symptoms Due to Tuberculous Process Itself *per se*.** That there are a few symptoms due to the tuberculous process itself is self-evident, and that they are probably the most important we have in early clinical tuberculosis is also evident, but we must not forget that they may at any time, and in any place, mislead us. The unfortunate part about these most important symptoms is the fact that as a general rule they appear later than do some of those due to the tubercular toxin and the reflex action of the toxin. They presuppose, either an involvement of some duration, or one of an area of considerable extent. In fact, when we make a diagnosis of clinical tuberculosis, it has, as a rule, existed for some time, and there is always a considerable area involved. These symptoms should be rarely mistaken for any other disease or condition. I wish, again, at the expense of repeating myself, to recall to your minds Evans' remarks upon the diagnosis of so-called incipient tuberculosis. It is in this group of symptoms, due to the tuberculous involvement *per se*, that we find the symptoms that are more definite and that help us more in reaching conclusions as to the process present in the diseased pulmonary tissue.

**Frequent and Prolonged Colds.** A history, and it is a common one, when a patient comes saying that it has been a winter or a spring of frequent and protracted colds, to get over one cold but to get another, means our bias toward the diagnosis, taken in conjunction with other symptoms or signs that may be present. I have been impressed during the last year with the num-

ber of patients who have come with this history, and presented, among other symptoms, a definite temperature curve, increased pulse rate, a little loss of weight, and perhaps night sweats. I am afraid that in many cases these attacks are passed over with the catch-all diagnosis of la grippe, but inquiry will usually show that these colds are not frequent attacks of grippe, but that they often start as a bronchitis and at other times as head colds, ending as bronchitis. A history of frequent and protracted colds with temperature elevation should always arouse suspicion and should call for most careful investigation, and physical examination.

**Hemoptysis.** Hemoptysis, or spitting of blood, with the possible exception of cough, is, perhaps, to the mind of the average medical practitioner, the most important and diagnostic sign that exists in tuberculosis. It is regarded by many that hemoptysis always means tuberculosis until proven otherwise.

Pottenger<sup>12</sup> says, "While there are other causes for this symptom, yet the fact that the patient raises blood is presumptive evidence that tuberculosis is present, and the evidence is conclusive in most cases when the blood is bright and mixed with sputum." Riviere<sup>14</sup> quotes Barnes as having found hemoptysis the initial symptom in 15% of cases, Bonney among 546 cases (20%), and Bartlett in only 6% among 400 cases. He further says, "The value of a well-marked hemoptysis is so great as to make this symptom, when well authenticated and other causes can be excluded, well nigh pathognomonic of tubercle. It is, then, of the utmost importance that with a free hemoptysis, other causes being excluded, phthisis should be presumed." Lord,<sup>15</sup> in a recent and most excellent paper, says that it is his belief that hemoptysis out of a clear sky is always tubercular in origin, whether symptoms and signs are present or not. In 307 cases of hemoptysis from the records of the Massachusetts General Hospital, all of them presumably tubercular, 30 came out of a clear sky, with no preceding sign or symptom, no pain, no dyspnea, no loss in weight, and no râles. Twenty of these 30 were found to be clinical cases of pulmonary tuberculosis; 10 came to autopsy, and all but one, or 90%, proved to be tubercular. I would, however, call your attention to this one case that did not prove to be tubercular in this series, for it represents 10%, and I think it is well for us to realize that there are perhaps other such cases as this one, in which any of us may at any time err in the matter of diagnosis.

I am very frank to state that, for one, I do not believe that every case of hemoptysis, with or without preceding signs or symptoms, is of necessity tubercular in origin, but that rather we should make every effort to make the diagnosis regardless of this symptom, and not let it cloud the issue, as it generally does. It would perhaps be well to mention the condi-

tions which may cause hemoptysis out of a clear sky, as well as tuberculosis, and there are many as Lord<sup>15</sup> gives them: 1, syphilis; 2, non-tubercular suppurations, abscess or gangrene; 3, echinococcus; 4, pneumonia; 5, pulmonary infarction; 6, aneurysm; 7, new growth. Lawson Brown,<sup>16</sup> in discussing Lord's paper made the statement that it was his opinion that every case of pulmonary hemorrhage should be considered as tubercular in origin until proved otherwise. There has been much discussion recently as to whether or not pulmonary hemorrhage may follow high blood pressure; it is believed by some that it is possible. I have never seen a case of hemoptysis due to this cause.

**Pleurisy.** Pleurisy with effusion has for many years been considered as always tubercular in origin by many, and of late the feeling seems to be growing that dry pleurisy should also be classed as tubercular until proved otherwise. I agree with this feeling, for every case of dry pleurisy that I have seen in the last five or six years has proven later to be tubercular.

**Sputum.** The question whether or not a person suffering from pulmonary tuberculosis should raise sputum or should not has been a source of controversy for many years, and there are those who still contend that it is necessary for sputum to be raised during the process of early active tuberculosis. The question of whether positive bacillary findings in the sputum are absolutely necessary before making a positive clinical diagnosis would seem to be too old for discussion, but that there are still many men who demand and insist upon tubercle bacilli being demonstrated before arriving at definite conclusions, though regrettable, is a fact. I believe that it is just as possible to make a definite diagnosis with a negative sputum as it is with a positive sputum, and a study of the records of the many State sanatoria would bear me out when I say that there are many patients in them, who do not show constant sputum findings, and there are many who, throughout the course of the disease, never give a positive sputum. In explanation of many of these cases, I would again bring to your attention Heise's<sup>11</sup> remarks regarding the two types of tuberculosis,—peribronchial and parenchymatous. In the former, tubercle bacilli were found in only 3%; in the latter, 47%.

**Temperature.** The last symptom considered in this third group has been described as under symptoms due to the tubercle toxin.

When any one of the first three symptoms found in this group, particularly if accompanied by one or more symptoms of this or either of the other groups, especially with elevation of the temperature curve occurs, we have strong presumptive evidence of clinical tuberculosis, whether any further evidence can be found or not, and with the manifestation of a positive tubercular reaction, we feel that we

are absolutely justified in making a diagnosis of active tuberculosis.

**Tuberculin.** A few words as to the use of tuberculin in the diagnosis of pulmonary tuberculosis. I am not quite in agreement with Lord,<sup>22</sup> who, speaking of the use of tuberculin subcutaneously, says, "I have been loath to use this test except as a last resort in diagnosis." Personally, I believe that tuberculin should be used to a wider extent in helping us to arrive at our diagnosis.

I believe, however, that it should always be used by one skilled in its use or under his personal direction, and not by the general practitioner, who at best understands its action so imperfectly. It would seem that needless chances are taken in administering large initial doses. An initial dose of from 1/10 to 1/2 milligram seems sufficient, with a gradual increase to 10 milligrams, increasing the dose every two or three days with the patient at absolute rest and taking a three-hour temperature chart.

Given certain symptoms in either of the three groups as mentioned by Pottenger,<sup>12</sup> with indefinite physical signs or none at all, I think that tuberculin injection is justified in many cases. If a positive result is obtained, its value depends upon the size of the dose to which the tissues responded. The smaller the dose required for temperature elevation, the greater evidence in favor of active disease.

Rivière,<sup>14</sup> speaking of tuberculin, says, "For each tuberculin test is compounded of many elements, some of which are of value, while others may be comparatively useless." Of the von Pirquet reaction he says, "No one, to take a concrete example, can in these days rely upon a positive von Pirquet reaction as evidence of active tuberculosis in the adult, and retain our respect for his intelligence; the vast mountain of fact is against him." I agree heartily with this characterization of the above, for from my own personal experience, I have found it of no value in adults, but of much in infancy.

**X-ray.** The value of the x-ray findings in the study of lesions of the pulmonary tract is a source of much controversy, and will always remain so. On the one hand, are those who maintain that it is possible to make a diagnosis of active pulmonary tuberculosis in the so-called incipient stage by means of the x-ray, in the absolute absence of any signs or symptoms; on the other hand are those who maintain that the value of the x-ray in the diagnosis of tuberculosis is negligible, and it is only as corroborative evidence that it is worthy of consideration. Between these two differing views, there are, of course, many men who lean to ward the one and toward the other.

Baetjer,<sup>17</sup> in a very sane paper on the "Early Diagnosis of Pulmonary Disease by the X-ray," read at the annual meeting of the National Association, said, "We cannot as yet

make a diagnosis between active and inactive tuberculosis, and, in my opinion, it is not advisable to send a patient away solely on the x-ray diagnosis." It was also his opinion that the radiogram could not make the diagnosis of early tuberculosis in the absence of signs or symptoms.

Minor<sup>18</sup> of Asheville summed up the situation very well when he said that, "Only in conjunction with physical signs or constitutional symptoms is a positive x-ray plate of any value, and in my opinion it is never wise or advisable to stand upon the x-ray findings alone." My personal opinion is that the value of the x-ray rests upon its use in corroborating the positive clinical diagnosis made by the clinician, and that it should be used in this way only.

This paper would be incomplete without some mention of the physical signs produced by the invasion of the lung structure by the tubercle bacilli. It has been well said that this bacillus is ubiquitous in every way, and in no more striking a manner than in the diversity of pathological lesions produced within the chest cavity. It is not my intention, nor within the scope of this paper, to take up your time with a discussion of the pathological conditions following its entrance, with which you are all acquainted. Perhaps the most important physical signs are the r le, localized or diffuse, dullness over the chest wall, and signs of consolidation, with transmitted voice sounds. Lawrason Brown<sup>19</sup> says, "The importance of physical examination in the diagnosis of pulmonary tuberculosis has been over-emphasized, and symptoms are a better and a more accurate guide to activity than physical signs." He also says, "Symptoms without physical signs demand treatment, while physical signs without symptoms require careful watching." I do not think the case could have been better put, and I agree with his opinion in this matter.

It does not seem to me that it is possible for physical signs due to the tubercle bacilli to exist in the lungs without definite symptoms, but I emphatically believe that the reverse is possible. I am sure, in my own opinion at least, that the tubercle bacilli may invade the lung tissue, producing certain changes productive of symptoms, such as given by Pottenger<sup>12</sup> in the first or second group, but without demonstrable physical signs. I am always exceedingly suspicious of a chest which shows dullness with r les, but in which the patient has no symptoms, suspicious that it is something other than tuberculosis. I cannot agree with him who demands a r le or dullness before making the diagnosis in the presence of a clear history of contagion and some symptoms, but I do agree with anyone who, in the presence of moderate or marked dullness, r le and cough, attacks of fever, but with no other physical signs, demands further study.

Bray<sup>20</sup> in a paper read at the annual meeting of the

that the râle is a very constant sign in incipient tuberculosis, and among the early physical signs the pulmonary râle is the one definite sign, the others merely represent deviations from the normal and, at most, are indefinite. He says that râles are latent in approximately 75% of early cases, and 30% of the moderately advanced; that localized apical râles are almost pathognomonic, other conditions that produce them being of rare occurrence. Glover<sup>21</sup> compares the various methods of diagnosis in tuberculosis of the lungs, particularly in regard to the distinction of active processes from inactive. Clinically, he attaches most weight to the presence or absence of râles, their absence, in his opinion, in repeated examinations excluding an active process. Rivière<sup>14</sup>, on the other hand, says that it is a common error to believe that small medium râles heard at one or both apices suffice for the diagnosis of phthisis. In practice this sign is frequently found in catarrh of all varieties of causation, and unless the râles are consonating, or there is an accompanying loss of percussion resonance, there is no justification for any diagnosis beyond that of catarrh.

I agree entirely with Bray<sup>20</sup> in his statement as to the value of the localized apical râle in the diagnosis of this condition and it seems to me that his figures are conservative and accurate so far as my personal observations, in that râles are latent, go. Let us always remember that the simple expedient of employing cough during the examination will bring these râles out. In the words of the elder Janeway (Bray), "Invariably employ cough to elicit râle in tuberculosis." However, notwithstanding my belief in the value of the latent râle, I still think it is unnecessary to insist upon its presence in all early cases or moderately advanced ones any more than I insist upon the presence of bacilli in the sputum. From my own personal experience, I know that it is possible for moderate or whispered dulness to exist without a râle, either before or after cough, and, taken in conjunction with history and constitutional symptoms, to mean but one thing,—pulmonary tuberculosis.

Just a few words as to breath sounds and voice sounds. Rivière<sup>14</sup> covers the ground exactly, I think, when he says that, "Voice sounds, and especially whispered voice sounds, should be compared with that derived from the breath sounds. As a rule, these signs cling together."

From the above discussion of the symptoms and signs of tuberculosis studied from the etiological standpoint, we can see, I am sure, that, if properly analyzed, they give us much diagnostic evidence. Those of the third group, due to the tuberculous process *per se*, are, of course, the most valuable. A history of frequent and protracted colds or hemoptysis or pleurisy, wet or dry, with a temperature curve, should cause us to investigate, always with an open mind. Alone, I am firmly convinced that the symptoms in the first and second groups do not defi-

nately mean tuberculosis. Associated with one or several of those of the third group, they are certainly worthy of the most serious and painstaking investigation. I confess that it is impossible for me to outline any sort of a symptom-complex or symptom-complexes to fit every suspected case: all I can say is that, in my opinion, it is ever necessary for each patient to be regarded as a distinct and separate one, analyzing the history, the constitutional symptoms and physical signs broadly and not permitting ourselves to be carried away by the presence of one or two signs or symptoms that may have been present in other patients in whom diagnosis of tuberculosis was proved. That there are certain symptoms that alone are of the greatest importance and value I freely admit. I cannot, however, bring myself to agree with the dictum that a patient be labelled for life as tubercular on such slender grounds as one symptom.

#### CONCLUSIONS.

In conclusion I should like rather briefly to review several of the points brought out in this paper and the convictions which I hold concerning them.

*In the first place*, I wish to emphasize again the belief that it is not only in the beginning cases of tuberculosis that we err in our diagnosis, but just as much in the diagnosis of the moderately advanced and advanced cases. I would urge you to consider the percentages of wrong diagnoses as cited by Ash<sup>6</sup> and the fact that during only the past year a matter of 1.6% of the individuals entering our State sanatoria were either non-tubercular or not diagnosed. Our responsibility is just as great in the diagnosis of the patient presenting with what seem to us all the necessary signs and symptoms for the diagnosis of advanced tuberculosis and I would urge upon you the necessity of approaching the examination in these cases with a mind as free and unprejudiced by the history of cough or hemoptysis as is possible, remembering that almost any pathological condition in the pulmonary tract may simulate tuberculosis in every respect.

*Secondly*, that Pottenger<sup>12</sup> in suggesting the consideration of the symptomatology from the etiological viewpoint has indeed made it easier to analyze the disease conditions.

*Thirdly*, that I feel from my own experience that Lawrason Brown,<sup>19</sup> and others more competent than I, are correct when they say that the importance of physical examination in the diagnosis of pulmonary tuberculosis has been over-emphasized in that symptoms are a better and a more accurate guide to activity than physical signs; that symptoms without physical signs demand treatment; that physical signs without symptoms require only careful watching. With symptoms and a history but no physical signs, I feel that we can make a diagnosis in the large

majority of cases; with physical signs but no symptoms, I feel that it is impossible.

Finally, it does not seem possible or probable that we can ever outline a symptom-complex of certain signs and certain symptoms and say that these signs and these symptoms in every suspicious case mean tuberculosis. It is rather my feeling that we must value each symptom and each sign for itself and in conjunction with other symptoms and other signs, for every case is a different one and has a different complex; and though deeming that certain outstanding symptoms, such as hemoptysis, cough, elevated temperature, increased pulse, and emaciation are suspicious of infection, I do not feel that we are qualified to say that this is a case of active clinical tuberculosis in an adult without proper and due consideration of the other factors present.

## DISCUSSION.

DR. HENRY D. CHADWICK, Westfield: I agree in the main with the statements in Dr. Schadt's paper, but I must take exception to some of his conclusions. I think he has very little basis for his conviction that as many patients are given an erroneous diagnosis of tuberculosis as there are positive cases that are wrongly told that

they are free from that disease. I do not think that the time has come that we can justly criticize physicians for their errors in that direction and do not see that he has produced sufficient evidence to support his contention.

The State sanatoria last year admitted 1629 patients, whom the physicians of the state had diagnosed as having pulmonary tuberculosis. Out of that number 12 were found, after prolonged observation and tests, to be non-tuberculous. That is only about .74% of error. Of the 2000 cases admitted to Westfield since 1910, 23 have been found non-tuberculous, or about 1%.

In what disease with which internal medicine has to deal can a better showing be made? To my mind that is a splendid record and the physicians of the state are to be commended for their accurate diagnosis of a disease which presents so many difficulties.

In connection with the 11½% of non-tuberculous cases found at autopsy by Dr. Ashe of Mattapan, I think the following quotation from his paper should also be taken into consideration. "It is not to be supposed that the same percentage of error extends to all cases that have been treated in the hospital. It would be lowered by those cases of undoubted tuberculosis that have been discharged otherwise than dead; and further, greater effort has been made to obtain permission for necropsy in those cases of special interest, among which have been a majority of the non-tuberculous. Furthermore, in eight of these cases tubercle bacilli have been found and the diagnosis had been made largely on this basis, in spite of any doubt that had previously existed as to the true nature of the case."

He states—and I agree with him—that when a diagnosis is doubtful, especially if the patient is in an institution, several sputum examinations should be made, and not put complete confidence in one positive finding. There are possible sources of error in labelling specimens and recording the findings, and also occasionally patients, to prevent discharge, will borrow specimens of sputum from a positive but generous neighbor.

Granting that a few patients are sent to a sanatorium under a mistaken diagnosis, the harm done, if any, is not to be compared to the fatal experience of too long delay while waiting for conditions to develop so far that the patient himself is able to decide that he has consumption. In doubtful cases I think patients should be sent to a sanatorium for diagnosis. These institutions should be used as clearing houses. Even if found negative, a patient's stay in such a hospital can do no harm and may be beneficial. If the diagnosis can be cleared up in this way great good results to the patient. Are not patients frequently sent to a general hospital under a wrong diagnosis? Of course accuracy in diagnosis is to be desired in all cases, but do not carry it to the point of putting the patient's life

in jeopardy by delaying until all positive signs are obvious. There would be fewer abdominal operations, but many more deaths, if surgeons waited for conditions to develop until a diagnosis was sure. Symptoms and physical signs are to be considered together in making a diagnosis. Physical signs do not distinguish the healed or latent lesions from one that is active. Symptoms, on the other hand, indicate the activity of the process and are to be considered almost exclusively in prescribing treatment. It is not necessary to send a patient away for treatment even when he has extensive physical signs if he had no symptoms of active tuberculosis. This should always be borne in mind when consulted by an ex-sanatorium patient, as not infrequently they are returned to sanatoria unnecessarily because of physical signs, but present no evidence of activity. If symptoms are present and physical signs cannot be made out, watch the case closely and without much delay consult with a specialist in chest diseases, whose better trained ear may be able to find a lesion before it has increased in activity or extent.

**Hemoptysis.**—This has been the initial symptom in 5% of the 1000 cases admitted to Westfield. I regard it, when present, as the most reliable of all the many symptoms of active tuberculosis. Don't give such a patient a sense of false security by saying the blood probably came from the throat unless you can prove that it does by finding the bleeding point. There will be fewer errors in diagnosis in such cases if, after excluding pneumonia, a positive diagnosis of pulmonary tuberculosis is made. Our percentage of arrested cases among those whose initial symptom was hemoptysis was equal to those having other symptoms at the onset.

Personal history is of the utmost importance, but the family history is of much less value, and especially is this the case with adults. Our records show that of 194 children under 14 years, 67% had a positive family history; in 209 patients from 14 to 20 years, it was positive in 44%; 815 patients over 20 years of age show but 34% with positive family history; therefore, it would seem to help but little in the consideration of the individual case.

Diagnosis should not be made on one symptom, but don't wait for them all. Neither form your conclusions on one pathological, physical sign, but don't wait for too many to develop. Consider all the evidence, giving the greatest weight to symptoms, exclude other possible diseases as far as you can, and then it is best to consider the case one of tuberculosis, and suitable treatment should be at once begun.

**DR. E. O. OTIS, BOSTON:** Those of us who are doing more or less special work in tuberculosis here in Boston frequently see and examine one another's patients as they go from one to another, and, as well, those who have consulted one or more dispensaries or out-patient departments. Sometimes we agree with the diagnosis

made by our brother physicians, or at the dispensary or hospital, and sometimes we disagree; which goes to show, it seems to me, that it is extremely difficult in at least a certain number of cases to make a definite diagnosis upon one examination. The only thing we can do is to keep the patient under observation until further evidence is obtained.

In teaching the subject of tuberculosis I have found that the tendency of the student is to place undue value upon slight physical signs, such as slight or doubtful dulness and slight modifications of the respiration. This is not infrequently the case with the practitioner. We need more than indefinite physical signs in order to make a definite diagnosis. We must have definite symptoms of an active disease. One must bear in mind the difference between clinical and anatomical tuberculosis. In the latter case, whatever the physical signs, if there are no symptoms and the patient is not ill, he requires no treatment; while in the former, if we have the characteristic symptoms and the patient is ill, whether we can detect definite physical signs or not, the case is one of clinical tuberculosis and should be treated as such.

With regard to hemoptysis, I believe we should regard this as almost a pathognomonic symptom with rare exceptions. It is true that one occasionally meets with cases of hemoptysis where there are no other symptoms or none subsequently develop.

I agree with Dr. Chadwick that more importance should be placed upon the personal history of the patient than upon the family history. In my experience I have found the former more valuable.

With regard to râles. As we all know there can be almost any amount of infiltration without evidence of moisture, indicated by râles. If, however, we find at an apex persistent fine râles it is one of the most, if not the most important of the physical signs we have, although it may not be the earliest sign. Here again, however, one ought not to make a diagnosis upon a single physical sign, even râles. We must have at the same time enough of the characteristic symptoms to complete the evidence in favor of tuberculosis—but with the râles and symptoms a positive diagnosis can generally be made. After all, there are not a few border line cases, which are not infrequently sent away, to the disarrangement of the family life, which, in my opinion, had better be kept under observation at home until more definite evidence is obtained. We have been insisting so persistently upon making an early diagnosis that the pendulum seems to have swung the other way and I have found with increasing frequency that the diagnosis of tuberculosis has been made and been reported upon what has seemed to me insufficient evidence.

**DR. GEORGE L. SCHADT, Springfield:** In regard to hemoptysis, I would not wish to be

understood as saying that in my opinion hemoptysis is not a very important symptom in early tuberculosis. My feeling, however, is that we should not let hemoptysis or any one symptom prejudice our minds to such an extent that we are willing to label an individual as tuberculous. It has been my experience in the last two or three years to see a number of individuals who have had pulmonary hemorrhages, apparently coming out of a clear sky, with no other symptoms following—no lesions, no temperature, no pulse—and every one of them has apparently recovered from whatever condition caused their hemorrhage. I am willing to admit, it might have been tuberculosis, but my feeling is still that we are not justified in labelling a person tuberculous on that one symptom with absolutely nothing else.

I must disagree with Dr. Chadwick when he says that it is his opinion that every case of suspected tuberculosis should be sent to the sanatorium for diagnosis. I disagree very strongly there. I do not think that you can make a comparison between the sending of a patient suspected of having tuberculosis to a sanatorium for diagnosis and the person suspected of having appendicitis to a general hospital. We look at it from different standpoints—he from the sanatorium point of view, I from the viewpoint of the practicing physician who comes in contact with the individual and with his family, and with the circumstances that ensue. It is the practicing or family physician who sees the after-results or opprobrium that comes to a person with a history of having been at a State sanatorium for tuberculosis whether he had the disease or whether he had not. I do not wish to go into the economic question; but I think it is little realized by the specialist, particularly by the sanatorium man, how much a history of having been an inmate in a State sanatorium for tuberculosis means to the individual in after-life.

Dr. Chadwick mentions 2000 cases admitted to the Westfield Sanatorium since its opening. In 23 of these there was found to be no tuberculosis, a little over one per cent. I think this is too much. I believe that we should not err even to one per cent. in the diagnosis of tuberculosis. I believe that by the proper correlation of our symptoms and our signs and our histories, personal and family, with the use of tuberculin, we could in pretty nearly every case make a definite diagnosis.

Dr. Otis emphasizes one of the points that I tried to make when he said that in his teaching he had learned a good many things: one thing commonest, that students are apt to over-emphasize certain points. I would emphasize that they are also apt to do carry these ideas into practice. That is over-emphasizing certain symptoms indicating the probable presence of tuberculous infection, but not necessarily tuberculous disease. I have seen these men come into practice, and with a history of cough or a history of

hemoptysis they have seen an indication of tuberculosis and nothing but tuberculosis. If a patient presents himself in the office and complains that he has had a cough for two or three weeks, or that he has expectorated a little blood, he is looked upon with the idea that tuberculosis must be found in him and not with the idea of simply forgetting the signs of hemoptysis, forgetting the cough and looking at the case in an intelligent manner, endeavoring to make a diagnosis with these symptoms as an aid and not because of the mere presence of these symptoms and nothing else.

## Medical Progress.

### ELEVENTH REPORT OF PROGRESS IN ORTHOPAEDIC SURGERY\*

By ROBERT B. OSGOOD, M.D., ROBERT SOUTTER, M.D.,  
HERMANN RUCHOLZ, M.D., HARRY C. LOW, M.D.,  
MURRAY S. DANFORTH, M.D., BOSTON.

#### TUBERCULOSIS.

ELY,<sup>1</sup> reviewing his results obtained in a series of experiments on eleven rabbits and six guinea pigs, concludes that "the lymphoid marrow of rabbit's bones is a good field for the growth of bovine tubercle bacilli, and that the lymphoid marrow of guinea pigs' bones is a good field for the growth of human tubercle bacilli."

These results would seem to cast doubt upon the correctness of Fraser's<sup>2</sup> dictum that red bone marrow is practically immune to tuberculosis.

Manning and Knott<sup>3</sup> have sought by means of the von Pirquet reaction to determine the percentage of children suffering from tuberculosis and living in known tuberculous families, contrasted with the percentage in children living under apparently favorable conditions. Of the first group (166), 50% gave a positive reaction. In the latter group only 22%. In the whole number (232), only 42% reacted to the test, which is a very much lower percentage than von Pirquet's figures, which were 93% in children of about the same age. The average percentage of positive reactions among fourteen observers who have studied large series of cases was 75%.

Wolcott<sup>4</sup> analyzes the results in 682 cases of Pott's disease in which an operation had been performed, the purpose of which operation was to ankylose the spine at the seat of the disease. On 642 cases either the bone graft, after the method of Albee, or the plastic bone operation,

\* This Report is based on a series of papers presented at the annual meeting of the American Orthopaedic Association, held at the Hotel Marlborough, Boston, March 1916. The papers are given only in outline, but the full text of each paper is available for reference and comment.

after the method of Hibbs, had been performed. In 198 cases, done by Albee himself, he has reported 92% as improved. In 158 cases done by Hibbs himself 90% were reported improved, and in 286 cases done by other surgeons there was improvement in 73%. In the whole series there were thirty deaths, or a mortality of about 5%. Three cases developed paraplegia after the operation, five cases developed abscess; there were nine cases of sepsis, and in seven there was necrosis of the graft. Tuberculous meningitis developed in seven and miliary tuberculosis in three. The conclusions of the author are: 1. The operation may be expected to abbreviate treatment and hasten ankylosis. 2. By hastening ankylosis the tendency to deformity is lessened. 3. The operations are best adapted for caries involving the cervico-dorsal, dorsal, and dorso-lumbar regions,—parts of the spine in which limited motion is of little consequence. It is less well adapted for caries involving the cervical and lumbar regions, parts in which limited motion is a detriment. 4. The general opinion of the majority of surgeons is that the operation should be considered only as one phase of the treatment for Pott's disease and that post-operative support should be continued until all signs of active disease have disappeared.

[Ed. Note.—With these conclusions the Editors find themselves in essential agreement. We are sorry that there has not been a more careful analysis of the relative value of the two operations in hands other than the originators of the two methods. Our own impression is that in the early cases with small kyphoses, the bone graft operation of Albee is likely to yield as good results as the plastic bone operation of Hibbs. It is an operation which requires less skill and its technic can be more easily acquired. It can be done more quickly and, especially if the motor saw is used, need induce little shock. If the kyphos is of considerable size, the bone graft operation is more difficult, and the cutting of a simple curved graft or the applying of a series of long, thin, bendable bone splints, consumes time and adds complexities. In spite of contention to the contrary, these grafts cannot in our experience be expected to lessen materially the size of the kyphos. The Hibbs plastic operation, on the other hand, does lessen the apparent size of the kyphos, and where complicated grafts would be necessary, can be done almost as quickly and, we believe, with as reasonable an expectation of ankylosis. In Dr. Hibbs' hands or in the hands of those who have taken the pains to develop a technic, there seems to be no more shock than in the bone graft operation. We attach great importance to the detail of the technic in order to obtain satisfactory results. We still feel doubtful concerning the wisdom of these operations under four to five years unless it is impossible to provide recumbency followed by am-

bulatory apparatus. We feel thus doubtful because the results of carefully carried-out conservative treatment are usually so good and because, with soft bones and rapid growth, we should feel that recumbent and protective treatment ought to be continued even after an ankylosing operation for a period approximately as long as that required in an ordinary case for healing by nature, aided by bloodless art. A 5% mortality is gratifyingly low, but not negligible.]

#### ARTHRITIS AND BURSITIS.

##### *Hemophilic Joints.*

DuPan<sup>2</sup> relates that a boy of fifteen was brought to the hospital on account of a very painful tumor of the ankle, which seemed to be a sarcoma on the point of ulcerating, except that sarcomata are not, as a rule, so painful. The tibia was not tender, and although there were local heat and fever, yet there was no involvement of glands, no lymphangitis or fluctuation. A small incision brought dark blood, but no pus, and the little cut bled continuously for three days, confirming the final assumption of hemophilia. Under calcium chlorid and diphtheria antitoxin the oozing of blood was finally arrested. His family showed the usual skipping of the second generation and the re-appearance of the hemophilia in the sons of the daughters, three of the five sons being pronounced hemophiliacs. In treatment the main thing is to suspect the hemophilia instead of mistaking the joint trouble for acute articular rheumatism or a tuberculous process, as is too often done. Du Pan declares that this error in diagnosis has often proved fatal. He cites various cases in which puncture of the joint for supposed hydrarthrosis has caused bleeding to death. The blood accumulating in the joint causes sudden pain and swelling, and the limb is held as in acute rheumatism. The region feels hot and there may be fever, but the skin keeps its normal color. There are, as a rule, several successive attacks involving different joints, but mostly the knee or elbow, one at a time, with or without some slight local trauma preceding. The hemarthrosis may be entirely absorbed, but it usually persists and irritates the joint, resulting in chronic arthritis. In the second phase this arthritis resembles in every respect a white swelling; there is thickening of the synovia, impotence of the limb, and wasting of the muscles. The pain is less in this stage, the swelling becomes more general, and the culs-de-sac are distended, but local heat does not increase. There is elastic fluctuation in the synovial culs-de-sac, as with a tuberculous process, and partial ankylosis develops. After the inflammation has subsided, insidious destruction may continue, and there is never an abscess or fistula, and never any enlargement of glands, as from malignant disease. There is danger of

mistaking hematomata in muscles for cold abscesses and of the occurrence of fatal hemorrhage resulting from incisions. The family antecedents and tests of coagulating power of blood will reveal the tendency to hemophilia. The first manifestations generally appear before the age of two and the hemophilias generally outgrow the tendency by twenty-two. It rarely happens that a hemophilia succumbs to hemorrhage after twenty-two. The most threatening hemorrhages are during teething or at puberty. The skin covering a hematoma is stretched, shiny, and bluish or black, with a peripheral red zone. These hematomata never suppurate, but the blood coagulated in them may undergo calcareous infiltration. The literature on hemophilia and the theories as to its mechanism are discussed in detail. Horse serum thus far has proved more effectual than anything else in the treatment of hemophilic cases, but its action is only transient.

### *Bursitis.*

Riedel<sup>6</sup> has made a study of an hygromatous affection of the bursa beneath the insertion of the semimembranosus tendon. The bursa does not as a rule communicate with the knee joint, but is separated from it by only a very thin membrane. From some unknown cause a serous or somewhat gelatinous exudate sometimes develops in this bursa, but this exudate is never as thick as the exudate of a tuberculous ganglion. Riedel estimates that in about one-third of the cases the thin membrane separating the bursa from the joint is ruptured by the exudate, and a chronic hydrops of the true joint may be set up. Great care must be exercised in excising the bursa, if opening the true joint is to be avoided.

### PARALYSIS.

#### *Decalcification of Bones in Paralyzed Limbs.*

H. Claude and R. Porak<sup>7</sup> have studied the phenomenon of bone decalcification in cases of paralysis of the upper extremity occurring from various causes, *e.g.*, paralysis uncomplicated by neuritis, paralysis from wounds of the brachial plexus, paralysis from hysteria and disuse from simple immobilization. Their conclusions are in keeping with those of Legg<sup>8</sup> and others. They believe it cannot be regarded as pathognomonic of any nerve lesion, but that the mechanism of its production is identical with that which causes the wasting of muscles, hyperkeratosis, local sweating, etc., and attributable wholly and solely to disuse.

### *Poliomyelitis.*

Sawyer<sup>9</sup> made a study of several groups of cases of epidemic poliomyelitis appearing in Northern California in the summer and fall of 1913. In many of the cases reported the infection can be explained on the theory that epidemic poliomyelitis is transmitted through con-

tact from acute cases or carriers. The active virus of poliomyelitis was demonstrated by animal inoculation to be present in rectal washings obtained from a patient fourteen days after the beginning of the paralysis. Since the active virus may leave the body from the rectum, as well as from the nose and mouth, precautions should be taken in the care of the poliomyelitis patient to prevent infection, not only from the nasal and buccal discharges, but also from feces and soiled bedding.

Abramson,<sup>10</sup> as a result of his examination of the spinal fluid in 43 cases of poliomyelitis, believes that a study of the etiology helps to distinguish the abortive and paralytic cases. No special help is afforded by this examination in the way of preventive or early treatment. Abramson states that the findings are often compatible with either poliomyelitis or tubercular meningitis, and lays emphasis upon the importance of the clinical signs, sudden onset, high fever, etc., in establishing the diagnosis. Thus far a study of the spinal fluid seems to offer little help in prognosis.

Francisco's<sup>11</sup> article on the early management of poliomyelitis is valuable in that it shows the great need which still exists of public education as to what is rational in the treatment of infantile paralysis. He investigated the previous treatment of thirty cases which came to his clinic and found that this treatment had been based on every type of ignorant and false advice. Some of it was mere quackery, there were many inefficient ready-made braces, and there was absolute neglect of treatment in other cases as a result of advice which had been given that "nothing could be done." Nearly all these cases were capable of being helped by operations or braces, but the great importance of the prevention of deformity was evident.

Gallie,<sup>12</sup> in his second paper, based on the results of 100 operative cases, feels justified in recommending the method of tendon fixation which he has advocated in cases of certain foot deformities and paralysis following poliomyelitis. He has discovered that it is necessary to remove the sheath of the tendon thoroughly before burying it in the groove made in the bone, else there is the possibility that the fixation will not be complete, the tendon moving in the sheath despite the fixation of the sheath to the bone.

Hoke and Hodgson,<sup>13</sup> as a result of their studies of the disabilities following poliomyelitis, believe that while tendon fixation, and perhaps the artificial silk ligaments of Lange, have their place in the treatment of the paralytic members, no operation on the soft parts is ever sufficient to hold the limb in good static position unless the bony skeleton is properly balanced. They, therefore, advocate bone operations whenever there is deformity or malposition of bone which would interfere with proper function or proper weight bearing.

[Ed. Note.—While the Editors are ready to admit the wisdom of bone operation in selected cases, they have been impressed with the amount of correction which may be obtained by tendon transplantation, tenodesis, silk ligaments, etc. Future growth may, perhaps, be expected to take care of a slight residual deformity if the operation succeeds in so balancing the foot that the resulting forces are exerted in a correcting direction.]

Biesalski<sup>14</sup> has operated on 9 cases of Little's disease; 3 four years old; 4 two and a half years old, 1 one year, 1 six months old, thus having a fairly long time of observation. The age was  $5\frac{1}{2}$  to  $12\frac{1}{2}$ . He has operated only on the most severe cases, and emphasizes the importance of selecting only these cases for this operation, as otherwise the results might be credited to Foerster's operation, which could be obtained with much simpler methods. Biesalski describes the technic of the operation, which he always does in one session.

### *Hemiplegia.*

Franz, Scheetz, and Wilson<sup>15</sup> report the results of massage, active and passive movements, in restoring motor function in old-standing cases of hemiplegia. From their observations it would appear that very considerable restoration of function can be obtained in many cases of hemiplegia by appropriate and persistent treatment. Their subjects were not altogether favorable, in that in several instances mental as well as physical impairment existed.

[Ed. Note.—The Editors wish to record, as they have done in previous Reports of Progress, their conviction that too little attempt is being made to ameliorate the depressing condition of these hemiplegic cases. A "shock" is looked upon by the public as an immediate forerunner of dissolution, and the immediate results of the shock are supposed to be permanent. Physicians, of course, know that often these patients live many years, and may die of an intercurrent disease without ever having another evident cerebral hemorrhage, and that often also very considerable recovery takes place. The years these patients do live will be much happier and more useful years if the idea of the hopelessness of the condition is combated, and the idea of a possible return of function under appropriate treatment and individual effort is fostered.]

### *Tardy Paralysis.*

Ramsay Hunt<sup>16</sup> reports three cases of late paralysis due to chronic progressive ulnar neuritis, developing years after injuries to the elbow. These injuries had produced a valgus deformity and some change in the ulnar groove. The paralysis is apparently due to pressure irritation of the nerve. In one of his cases part of this pressure, at least, was due to a bursal cyst developing in the groove beneath the nerve. Excision of this cyst brought relief of the paraly-

sis. The necessity of differentiating this condition from the progressive spinal atrophies is obvious.

### BONE AND JOINT SURGERY.

Haas<sup>17</sup> has carried out a series of 75 experimental transplantations of the epiphysis. These consisted of eleven transplantations of an entire metacarpal or metatarsal, ten autotransplantations of the same, four reimplantations of split metacarpal or metatarsal, two autotransplantations of the same, six reimplantations of the epiphyseal cartilage, seven autotransplantations of the same, twelve reimplantations of varying lengths of the epiphyseal end of the metacarpal and metatarsal bones, twelve autotransplantations of the same, and ten two-stage autotransplantations of the same. The author draws the following general conclusions: 1. From the practically uniform failure of increase in length of the bones after transplantation of the epiphyseal cartilage, either alone or with an accompanying piece of the epiphysis and diaphysis, both in reimplantation and autotransplantation, it must be concluded that epiphyseal cartilage loses its power to function after such transplantations. 2. As the degenerative processes were more advanced in autotransplantation than in reimplantation, it can be almost certainly predicted that there would be a more marked degeneration in homotransplantation. 3. Whether a small- or large-sized transplant was taken was of no consequence, as there was the same failure of growth in every instance. Incision into the periosteum or boring holes into the cortex hastened the degenerative process. 4. There was marked disturbance of growth following the two-stage autotransplantation, in spite of the fact that osseous union was secured before severing the epiphyseal transplant from its surrounding and nourishing tissues. 5. The epiphyseal cartilage must be considered as a very vulnerable tissue, its viability being directly dependent upon its blood supply.

### *Bone Transplantation.*

Horak<sup>18</sup> reports two cases of extensive osteoplasty of the humerus after removal of bone for sarcoma. In the first case the upper two-thirds were removed and a piece of the humerus of a seventeen-year-old girl, who had died from a gunshot wound in the head, substituted for the resected portion. The result was fairly good; the patient became able to move the shoulder up to the horizontal line, and to use the arm for eating and sewing. In another case the lower part of the diaphysis of the humerus was removed and a piece from the humerus of a young man who had died also from a gunshot wound in the head was implanted. Four days after the operation the patient showed symptoms of tetanus, from which he died. Tetanus bacilli were found in the marrow of the trans-

planted bone. This unfortunate occurrence makes evident the necessity for a most careful bacteriological examination of the blood and bone marrow in all homeoplastic operations in which the transplant has not been boiled. Küttner has already pointed out the importance of such examination.

Williams<sup>19</sup> reports an interesting case in which a giant cell sarcoma occurred in a man 27 years old, and 2½ inches of the lower end of the radius were excised. Two days later they obtained from a suicide the lower end of the radius, which was boiled an hour and kept in sterile salt solution for four days. This graft was applied and primary union took place. Subsequent x-rays showed the hand radially abducted and dislocation of the ulna. The function was poor and the hand grasps weak. The graft seemed to have acquired definite contact with the living bone.

[Ed. Note.—We have noticed this deformity and lack of good function in certain cases where similar operations have been done.]

#### *Subperiosteal Resection in Osteomyelitis.*

In a series of experiments in dogs, Phemister<sup>20</sup> finds that in young animals after subperiosteal resection of the shafts of the same bones that are most commonly affected by osteomyelitis in man, for example, the tibia and the humerus, there is usually a complete regeneration of the shaft. From his study of the specimens subsequently removed, it seems that the periosteum plays a certain part (osteogenetically) in the formation of the new bone, though the particles of bone remaining adherent to the periosteum after the removal of the shaft play a part also. In old dogs after subperiosteal resection, using the same technique, there was almost invariably failure of regeneration. Infection even in young animals greatly delayed or prevented the regeneration. Clinically, also, he finds that age is an important factor. He considers that "in view of the clinical and experimental data now at hand, showing the frequent failure of regeneration, subperiosteal resection should be reserved for selected cases of osteomyelitis in which there has been extensive necrosis of bone and particularly where this necrosis is located in areas inaccessible to operation, such as the posterior part of the tibia. Its use should be limited to parts of the body in which there is some other bony support (a so-called 'splinting' bone) and should almost never be used where there is only one bone in the extremity, as late sequestrectomy gives better results in such cases." The operation should not be performed too early, while the infection is severe, nor before a soft involucrum has formed. On the other hand, it should not be performed too late, after the involucrum is so ossified that an insufficient amount of osteogenetic tissue remains.

#### *Excision of Transverse Process of Fifth Lumbar Vertebra.*

Fassett<sup>21</sup> reports three cases in which an excision was done after other methods, such as fixation in various ways, had been tried. In these cases he exposed the process, either by direct incision through the erector spinae muscle or by a curved incision, turning back skin and muscle flaps toward the mid line. Removal was done by blunt dissection and chisel. Very material improvement resulted in all three cases. In one of these three cases symptoms developed on the other side subsequently, and the transverse process was removed on that side, but too little time had elapsed to admit of any conclusions. From these cases, and from others reported, it would seem that excision of the transverse process of the 5th lumbar must be considered in certain persistently painful backs of the type described.

Clarke<sup>22</sup> records an interesting case in which expert roentgenological interpretation had diagnosed a malignant sarcoma of the femur, but in which at the time of operation he was induced by the macroscopic appearance of the neoplasm, which suggested a "fibrous cyst," to withhold radical measures. After removal of the growth he approximated the parts with a bone graft and a long Lane plate. Subsequent pathological study confirmed the wisdom of his judgment.

[Ed. Note.—As Clarke says, it is most difficult at times to determine from the x-ray whether to call a bone tumor a cyst or a giant celled sarcoma, and the question we believe is still open as to just how many giant cells make it a sarcoma and just how definite a cavity must exist to call it a bone cyst. The "enraptured jelly" material and the many crossing and irregular trabeculae belong to more serious so-called giant celled sarcoma. As Bloodgood has shown, neither condition is malignant in the sense of metastasis. Both are usually capable of cure by local extirpation, and there is strong evidence to prove that many bone cysts "cure themselves," especially if they are broken, and certain evidence to suggest that occasionally an apparently typical giant celled sarcoma may disappear without radical excision. Fortunately, periosteal sarcomata are usually easy to differentiate in the x-ray from the less malignant form, but Clarke's article certainly emphasizes the necessity of most careful investigation as to the malignancy of bone tumors before amputations are performed, especially since the percentage of recurrences in the periosteal sarcomata is so high, even after most radical procedures.

#### *Pseudarthrosis of the Forearm.*

Novik-Jossorand<sup>23</sup> has observed that pseudarthrosis of the forearm does not as a rule occur when both bones are treated by the same method, most common in compound fractures of the radius or the ulna alone, but less frequent in

The author considers the separation between the ends of the bone the cause of non-union, and where the gap is less than 4 cm. recommends shortening the intact bone by an oblique cut, and thoroughly freeing and freshening the ends of the non-united bone and bringing them into apposition.

#### *Irrigation of Joints.*

Churchman,<sup>24</sup> after laboratory experimentation, has developed a technic by which joints may be irrigated thoroughly and repeatedly under local anesthesia. His apparatus, which consists of a series of aspiration bottles, is described, and he believes that he has benefited thus a few cases of tuberculous and Neisser joints.

#### RICKETS.

Baumann<sup>25</sup> describes a case of so-called myopathia rachitica, an affection of the muscles in rickets, which has been known since 1904 through the studies of Hagenbach-Bueckhardt, but which has not found very common consideration in literature. The case of Baumann's was a child of about three months, with typical signs of rickets. There was thickening of the epiphysis in both forearms, and both arms were paretic; there were no motions noticeable in the left hand, and only very weak and slow motion in the right hand. There was hyperextension of the elbow. When the arms were elevated, they fell down as though paralyzed, but fell in a more retarded manner. The muscles seemed to be tender. The electrical examination showed very considerable decrease in the electrical irritability by the faradic, as well as the galvanic current, but the changes were only quantitative and not qualitative. Under physical therapy the conditions improved. Indeed, it has been stated that physical therapy is of such benefit in these cases that the affection of muscles is often cured before there is any apparent change in the bony signs. Baumann presents illustrations of histological findings of another case, which show a very indistinct structure of the muscle fibres. In severe cases the cross stripes are particularly indistinct, while the longitudinal stripes are still seen. The kernels are enormously augmented in number. The differential diagnoses must include: 1. Acute polymyositis. 2. Polyneuritis. 3. Paralysis following acute infectious diseases. 4. Antero-polio-myelitis. 5. Myotonia congenita. 6. Secondary muscular atrophy. 7. Idiocy and myxedema.

(To be continued.)

PROGRESS OF POLIO-MYELITIS EPIDEMICS.—On August 25 the number of cases in the New York epidemic of poliomyelitis reached a total of 7,621, with 1,785 deaths. In Massachusetts on that date, the total number of cases since August 1st was 203, of which 38 have been in Boston. There have been 328 cases in this State since January 1, 1916.

## Book Reviews.

*Emergency Surgery.* By JOHN W. SLUSS, A.M., M.D., Associate Professor of Surgery, Indiana University School of Medicine; Ex-Superintendent Indianapolis City Hospital; Surgeon to the City Hospital. Third edition, revised and enlarged with 685 illustrations, some of which are printed in colors. Philadelphia: P. Blakiston's Son & Co. 1915.

This is a small book of 800 pages, well bound, well printed and illustrated. In the preface to this third edition, the author remarks that he has "adhered to the aim of former editions to present general principles concisely, and practical details amply—in short to make a book useful to the general practitioner in the surgical phase of his daily routine." Besides a careful general revision, the subject matter of Fractures has in this new edition been increased—and War Surgery rewritten. The book seems to be a good compilation of standard works, without bibliography. It has, in common with similar books, a tendency to help the untrained general practitioner to believe that surgery is really easy and may be done safely by almost any doctor. It is an open question whether such books do more harm than good, especially when, like this one, they are attractive in appearance and dogmatic in statement.

*Practical Cystoscopy and the Diagnosis of Surgical Diseases of the Kidneys and Urinary Bladder.* By PAUL M. PILCHER, M.D., Consulting Surgeon to the Eastern Long Island Hospital. Second edition, thoroughly revised and enlarged. Octavo of 504 pages, with 299 illustrations, 29 in colors. Philadelphia and London: W. B. Saunders Company. 1915.

The first edition of this book was published four years ago. The demand for a new edition has brought out the present volume,—a book twenty-five per cent. larger than its predecessor, thoroughly revised, and brought up to date by the rewriting of several chapters, notably those on "Diseases of the Prostate" and on "Functional Activity of the Kidneys." A new section of twenty-five pages on Pyelography has been added. The final chapters of the book, devoted to "Therapeutic Uses of the Cystoscope" have been greatly amplified. They contain among other new work, a detailed description of the use of the high frequency current in the treatment of bladder tumors.

The publishers have maintained the high standard of paper, type and illustration which made the first edition so attractive, and the book continues to be, as was its first edition, an example for other writers to follow.

## THE BOSTON Medical and Surgical Journal

Established in 1812

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, AUGUST 31, 1916

## EDITORS.

ROBERT M. GREEN, M.D., *Editor-in-Chief*,  
GEORGE G. SMITH, M.D., *Assistant Editor*,  
WALTER L. BURRAGE, M.D., *For the Massachusetts Medical Society*.

## COMMITTEE OF CONSULTING EDITORS.

WALTER B. CANNON, M.D., ALLAN J. McLAUGHLIN, M.D.  
HARVEY CUSHING, M.D., ROBERT B. OSGOOD, M.D.  
EDWARD L. EDSELL, M.D., MILTON J. ROSENBAUM, M.D.  
REID HUNT, M.D., EDWARD C. STREETER, M.D.  
ROGER I. LEE, M.D., E. W. TAYLOR, M.D.

## ADVISORY COMMITTEE.

EDWARD C. STREETER, M.D., *Boston, Chairman*,  
WALTER P. BOWERS, M.D., *Clinton*,  
ALGERNON COOLIDGE, M.D., *Boston*,  
HOMER GAGE, M.D., *Worcester*,  
JOEL E. GOLDSWORTHY, M.D., *Boston*,  
LYMAN A. JONES, M.D., *Boston*,  
ROBERT B. OSGOOD, M.D., *Boston*,  
HUGH WILLIAMS, M.D., *Boston*,  
ALFRED WORCESTER, M.D., *Waltham*.

**SUBSCRIPTION TERMS:** \$5.00 per year, in advance, postage paid, for the United States. \$6.50 per year for all foreign countries belonging to the Postal Union.

An editor will be in the editorial office daily, except Sunday, from twelve to one-thirty p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, Manager.

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

## THE LATEST THING IN CRUTCHES.

NECESSITY is the mother of invention and war is the mother of necessity. Therefore, war is the grandmother of invention and certainly the present war has seen a great many grandchildren, most of whom exemplify the saying that heredity skips a generation by being quite martial in nature. One of the latest products of the war is the ingenious device of a French engineer by the name of Schlick, to take the place of the old style crutch slung under the armpit.

The disadvantages of this aid to locomotion have always been obvious. The weight and pressure, coming as they did in the axillary region, a spot not designed by nature for them, caused in some individuals boils, in others pareses as the result of pressure on the large nerve trunks. Then, too, practically all weight was taken off the injured limb, which was prejudicial to the recovery of function.

The new invention resembles a walking stick

with a horizontal handle. Above the handle is a spring rest sloped to fit the forearm. In use part of the body weight on that side falls upon the hand and wrist, the rest is borne by the injured leg and the balance of the weight can be shifted back and forth as conditions require.

This crutch has been on trial about a year now and has been commended very highly by wounded soldiers who have tried it. It is said to be so simple and natural in its application, that proficiency in its use can be acquired in half an hour.

Preparedness should certainly include a familiarity with the merits of this new crutch; for, should war come, not the least of its problems would be the care of the crippled.

## THE EFFECT OF THE WAR ON THE YOUNGER GENERATION IN GERMANY.

In view of the many conflicting statements which have appeared relative to the effectiveness of the Allied Forces' blockade, it is interesting to hear a report which appears to be impartial, being gloomy in spite of coming from a German source. Dr. A. H. Kettner, school medical officer in Charlottenburg, takes rather a pessimistic view of the health of the school children in his district. He states that it was only half a year after the opening of the war that the adults of the working classes became underfed. At first the children did not suffer, as their parents made sacrifices for them, believing that the war would be of short duration. Then, too, the government subsidized nursing mothers, which relieved the situation somewhat.

Dr. Kettner's present report is especially interesting for the reason that in the spring of 1915, he stated that the war had made no difference in the health or development of the children. But later on he was obliged to revise this opinion when the children were weighed and measured, as is done annually. Increase both in height and weight was found to be checked, particularly among the girls. Dr. Kettner also reports an increase in two diseases of childhood, rickets and tetany. The former was, of course, easily accounted for by the poorer food supply since the war; the latter is supposed to be due in a large measure to the effect of the blockade of war upon the production of vitamin D.

The above report, emanating as it does from a German official, contrasting no doubt with what he would prefer to report and directly opposite to his previously expressed opinion, must be given considerable weight. It would seem to show that, while the Central Powers are able to feed themselves indefinitely, the nutritional quality of their subsistence must be somewhat impaired as a result of the state of war existing, and this deficiency will be felt more keenly where there is the least resistance, that is, among the younger generation.

### MEDICAL ASPECTS OF SHAKESPEARE'S GENIUS.

THE recent observance of the tercentenary of Shakespeare's death has recalled to the public mind, not only the poet himself and his works, too often neglected, or even forgotten, but also many of the books and comments that have been made or written about him. Among the many aspects of Shakespeare's genius which have been thus reviewed and considered, naturally the most pertinent to our profession is that which deals with his medical knowledge and references. Much on this subject has been written in time past; and without attempting a complete review of this literature, we may refer briefly to a few of the former and recent articles which have appeared on this topic.

In 1906 Dr. John W. Wainwright of New York published an admirable monograph consisting of a compilation of quotations from Shakespeare's plays illustrating the author's medical and surgical knowledge. This work of avocation by a busy physician constitutes a valuable contribution, which only one with a professional training could make, to the elucidation of many Shakespearean quotations and to our knowledge of the poet himself and of his mental and scientific background.

In the issue of the JOURNAL of January 17, 1907 (Vol. clvi, p. 65), is a further contribution by a physician, Dr. Albert C. Getchell of Worcester, Mass., on "The Medical Knowledge of Shakespeare," which presents, in a similar fashion to that of Dr. Wainwright, a series of grouped quotations illustrating Shakespeare's knowledge of medicine and surgery. We cannot do better than to refer readers to these two publications for complete perusal. In the issue of the JOURNAL for April 18, 1912 (Vol. clxvi, p. 603), we also commented editorially on Shake-

speare as a medical observer, calling attention particularly to the astounding accuracy of his scientific as well as his artistic perceptions.

In an issue of the *Westminster Review* some years ago, and not now available for verification of the reference, was an article by Dr. John Knott on "The Medical Knowledge of Shakespeare" in which he cites the following quotations as evidence that Shakespeare's knowledge of the circulation of the blood was really in advance of Harvey's demonstration.

"The second property of your excellent sherris is the warming of the blood, which, before cold and settled, left the liver white and pale, which is the badge of pusillanimity and cowardice; but the sherris warms it and makes it course from the inwards to the parts extreme. It illumineth the face, which, as a beacon, gives warning to all the rest of this little kingdom, man, to arm, and then the vital commoners, and inland petty spirits, muster me all to their captain, the heart; who, great and puffed up with his retinue, doth any deed of courage; and this valne comes of sherris. . . "

In the play of *Coriolanus*, the stomach, replying to the attacks of its enemies, proceeds to say:

"True is it, my incorporate friends," quoth he, "That I received the general food at first, Which you do live upon; and fit it is, Because I am the store-house and the shop Of the whole body; but, if you do remember I sent it through the veins of your blood, Even to the court, the heart; to the seat o' the brain;

And through the cranks and offices of man, The strongest nerves and small inferior veins From me receive that natural competency Whereby they live."

Another medical aspect is that of Shakespeare's doctors, which was excellently discussed some years ago in a paper by Dr. P. S. Donnellan of Philadelphia, to which the reference cannot now be found. Dr. Donnellan pointed out that,

"Shakespeare's references to the medical profession are characterized by almost unvarying respect; indeed, it would be difficult to find in the works of any non-medical author a higher ideal of the physician and his calling than he gives us. Only in two well-known instances does he hold the physician up to ridicule. Once, in 'The Merry Wives of Windsor,' in the character of Dr. Caius, whom Dame Quickly declares is a combination of the fool and the physician, and who is supposed to be a burlesque on Sir Theodore Mayerne, a French doctor who was expelled from the College of Physicians in Paris in 1603 because of his 'rashness,

impudence and ignorance of true physick.' The second instance is that of Dr. Butts in 'Henry VIII,' but he is shown as a courtier rather than a physician.

"The physicians who were the creations of Shakespeare's brain were portrayed as men of high character and skilled in the practice of their time. In 'Lear' the doctor is an expert alienist and neurologist, and manages the case of the demented monarch with such tenderness and skill as to earn the gratitude of the devoted Cordelia. In 'Macbeth,' the physician who is called upon to attend Lady Macbeth in her mental collapse following the murder of 'the unguarded Duncan,' proves himself at once a shrewd Scotsman and a tactful practitioner. Before he undertakes 'to minister to a mind diseased' or 'pluck from the brain a rooted sorrow,' he cautiously finds out from her gentlewoman-in-waiting the exact condition of his royal patient, and honestly admits 'she more needs the divine than the physician' to soothe her distressed conscience; that her disease is beyond his practice, and after giving her attendants some good advice to watch her carefully and 'remove from her the means of all annoyance,' he prudently withdraws."

In England the occasion of Shakespeare's tercentenary was chosen by Dr. Sir St. Clair Thomson to deliver the 141st annual oration of the Medical Society of London, May 1, 1916, on "Shakespeare and Medicine." This oration was quoted and reviewed at some length in *The Medical Press and Circular*.

"In Shakespeare's time, medical science was but emerging from the chaos of unlicensed and irregular practice, and the marriage of his eldest daughter, Susanna, to Dr. John Hall, of Stratford, afforded his keen observation the requisite opportunity to note the habits and ways of thought of medical men. Quacks, male and female, flourished then as now, and such practice was indeed encouraged by the fact that the regular physician was apt to cease attendance on a case he considered incurable, to save his reputation. Physic failed to minister to a mind diseased, to pluck from the memory a rooted sorrow, and to raze out the written tablets of the brain (Macbeth), and an allusion to auto-suggestion may be read into the recommendation of the patient to 'minister to himself.'"

"The works of Shakespeare contain references to ague, rheumatism, plagues, pestilence, fever, measles, 'the sweat,' leprosy, apoplexy, bone-ache, colic, consumption, convulsions, cramps, dropsy, ecstacy, epilepsy, gout, green sickness (chlorosis), heartburn, hemiplegia, hydrophobia, itch, jaundice, palsy, sciatica, senile senility, somnambulism, and visual spectra."

"The poet shared the common belief that vital spirits dwell in the arteries, and that wound trouble is attributable to the access of

air, an interesting observation regarding sepsis which recalls Lister's carbolic spray. His references to the circulation of the blood in 'Hamlet' and 'Measure for Measure' notably are prophetic, seeing that Harvey did not reach his famous conclusion until a week before Shakespeare's death. The social disease, on which a Royal Commission has recently reported, was known in Shakespeare's day variously as 'the French disease,' and 'the Neapolitan disease.' Great as was his belief in the benefits of fresh air, he still regarded night air as harmful:

"And will he steal out of his wholesome bed  
To dare the vile contagion of the night,"

"The passage in 'Macbeth':

"... Macduff was from his mother's womb  
Untimely ripp'd."

seems to indicate the practice at that time of Caesarean section.

"Shakespeare was deeply interested in mental pathology." He shows surprising knowledge of the mental confusion preceding an epileptic attack, and of the ensuing maniacal excitement. He alludes to the value of music in sickness, but hints the influence is not always beneficial, for he states that emesis may result from the sound of the bagpipes. We believe this is not unknown in enemy ranks when Scottish regiments get to work. And the untutored Southron says there is no music in the bagpipes! The genius of our greatest Englishman is clearly revealed in his insight into mental and nervous disorders, as witness the neurasthenia of Hamlet, the melancholy of Jacques, the excoimby of Malvolio, the hallucinations of Macbeth, the insane ambition of Lady Macbeth, the insanity of Ophelia, the maniacal misanthropy of Timon of Athens, the blind fury of Othello, the frenzy of Constance, the mania of King Lear, and the foolish imbecility of Simple, Shallow, and Speed. In 'As You Like It' we get a good idea of the way in which bad cases of madness were treated (the mild cases were not segregated).

"Love is merely a madness, and I tell you, deserves as well a dark house and a whip as madmen do."

"In 'Much Ado about Nothing' we find a foreshadowing of the principles which underlie the modern and kindly treatment of the mentally afflicted."

The issue of the *British Medical Journal* for May 6 contains a further report of Dr. Thomson's address, particularly with reference to the character of Shakespeare's physicians.

"Out of thirty-six plays, medical characters were represented six times: 1. Dr. Caius in 'Merry Wives of Windsor'; 2. Dr. Fluellen, doctor; and 3. A Scottish doctor in 'Henry VIII.'"

4. Dr. Butts in 'Henry VIII.' 5. Dr. Pinch in 'Cymbeline'; and 6. Dr. Ross in 'King Lear.' No other characters were named as physicians. Dr. Caius was the only one who was a

than as a regular physician, and it was probable that Shakespeare meant to represent a quack and not the learned Dr. Caius. Dr. Cornelius was possibly suggested by the famous physician of Charles V and simply adapted for dramatic purposes. The Dr. Butts represented in the fifth act of 'Henry VIII' was no doubt Dr. William Butts, Fellow of Gonville Hall, Cambridge, and of the College of Physicians, who lies buried in Fulham Church. Cornelius played with honour and astuteness a difficult part when the Queen asked him for poison, and the physician of King Lear played his part well and sympathetically. Cerimon in 'Pericles' was both a physician and a nobleman, so that the good social status of the medical man was here accepted and illustrated. No nobler panegyric of our profession could be written than that put in the mouth of Cerimon.

"Quacks, who flourished abundantly in the period, were portrayed in several plays. Among such characters were Pinch, Friar Lawrence, and Helena. Quacks and medical mountebanks were found in the earlier plays, and the first practitioner of medicine for whom Shakespeare did not entertain contempt was the physician in 'King Lear,' which was written about 1606, the year before the poet's daughter married Dr. Hall."

Finally, in the issue of the *Scientific Monthly* for June, 1916, has been published an article by Dr. James Frederick Rogers, of New Haven, Conn., on "Shakespeare as a Health Teacher." It is still another aspect from which this many-sided genius may be considered, to regard him as an early proponent of personal and communal hygiene. Though not in any sense, however, a student of sanitation, it is obvious that for his generation he had a keen insight into the nature of physical and mental health, and the causes and habits that may improve, maintain or injure it. Dr. Rogers illustrates these propositions also by quotations from the plays, and concludes that Shakespeare was, in the most important sense, a teacher of hygiene, standing among the foremost in the goodly company of non-professional writers, such as Plato, Cervantes, Molière, Montaigne, Bacon, Locke, Addison, Franklin, Carlyle, Spencer and others, "who, by both precept and practice, have been our greatest preachers of the gospel of health."

#### MEDICAL NOTES.

PROGRESS OF POLIOMYELITIS.—In the issue of the *JOURNAL* for August 17, we discussed editorially the use of immune serum from recently recovered cases in the treatment of acute polio-

myelitis. Report from New York on August 15, states that Dr. Abram Ziegler, of the Willard Parker Memorial Hospital in that city, advocates the similar use of normal serum from parents.

Report from Toronto, Canada, on August 15, states that poliomyelitis is increasing in prevalence in the province of Ontario. During June, 1916, there were two cases and no deaths; in July, eleven cases and two deaths; and during the first fortnight of August, eight new cases of the disease were reported. Of all Canadian provinces, Ontario is in most immediate communication with New York and Chicago.

Report from London on August 15 states that poliomyelitis is at present also epidemic in Aberdeen, Scotland, where 39 cases have occurred since July 1.

OCCUPATIONAL DISEASES.—At the meeting of the American Chemical Society in New York on September 25 to 30, there will be conducted a symposium on Occupational Diseases, presided over by Professor Charles Baskerville, head of the department of chemistry of the College of the City of New York.

The symposium will consider the chemical trades, prophylaxis in chemical industry, diseases incidental to work in aniline and other coal tar products, cedar lumber, mines, explosives, and a general discussion by the leading authorities of the country. These will include Drs. W. Gilman Thompson, F. L. Hofman, J. W. Schereschewsky, G. P. Adamson, H. N. Benson, W. A. Lynott, Alice Hamilton and Mr. J. B. Andrews.

THE CARTWRIGHT LECTURES.—The Cartwright Lectures for 1916 of the Association of the Alumni of the College of Physicians and Surgeons, Columbia University, will be given by Dr. Richard M. Pearce, professor of research medicine, University of Pennsylvania, on October 24 and 25. Professor Pearce's subject will be, "The Spleen in Its Relation to Blood Destruction and Regeneration."

DR. WELCH SAILS FOR ENGLAND.—Dr. William H. Welch sailed from New York on August 6 for England, to make studies in connection with the organization of the school of hygiene and public health established by the Rockefeller Foundation at the Johns Hopkins University. Dr. Welch will also study, as president of the National Academy of Sciences, the manner in which England has been organized in scientific lines for the war. He is accompanied by Dr. George Ellery Hale, chairman of the committee of the academy on scientific organization.

#### EUROPEAN WAR NOTES.

GERMANY AND RED CROSS SUPPLIES.—In last week's issue of the *JOURNAL*, we noted at length the refusal of the British Government to permit the passage of Red Cross supplies from America to the Central Empires. On August 9, the German Government issued the following memo-

random, outlining its future policy towards such supplies destined for the Allied Powers, in view of this refusal:

"Great Britain, although she had originally assented to safe passage of such articles, having declined to accept the proposals of the American and Spanish governments, having even refused to allow the American Red Cross organization to dispatch them, to the German Red Cross Society, and having further declined to listen to a protest from former President Taft on the subject, Germany is no longer in a position to grant free passage of surgical and medical requisites coming within the power of her naval forces, as she has done up to now. The German navy will receive orders to exercise in the future the right pertaining to it to requisition the medical and surgical requisites mentioned in the Spanish government's list for the use of German military forces."

#### MEXICAN NOTES.

THE AMERICAN RED CROSS has been informed by the War Department that the Quartermaster's Department will make a gratuitous issue of colored glasses, or goggles, to the troops on the Border for the protection of their eyes from glare and sand. In view of this, Major-General Arthur Murray, Acting Chairman of the Central Committee, American Red Cross, announces that it will not be necessary for these to be contributed by Chapters or other Red Cross agencies.

#### BOSTON AND NEW ENGLAND

**HARVARD SURGICAL UNIT.**—Another reinforcement for the Harvard Surgical Unit at the front in France sailed from New York on August 17, aboard the steamer *Lupland*. The new detachment consisted of 11 surgeons and 11 nurses. Dr. Daniel Fiske Jones is the surgeon in charge.

**BEQUEST.**—By the will of Mrs. Josephine Angier Binney, of Providence, R. I., the Sharon Sanatorium has recently received a bequest of \$3,000.

**THE WEEK'S DEATH RATE IN BOSTON.**—During the week ending August 19, 1916, there were 222 deaths reported, with a rate of 15.22 per 1,000 population, as compared with 206 and a rate of 15.75 for the corresponding week of last year. There were 53 deaths under one year as compared with 51 last year, and 48 deaths over 60 years of age against 68 last year.

During the week the number of cases of principal reportable diseases were: Diphtheria 38; Scarlet fever 8; Measles 23; Whooping cough 18; Typhoid fever 2; Tuberculosis 57.

Included in the above were the following cases of non-residents: Diphtheria 4; Scarlet fever 4; Tuberculosis 5.

Total deaths from these diseases were: Measles 5; Whooping cough 2; Tuberculosis 23; Anterior Poliomyelitis 4; Typhoid fever 1.

Included in the above were the following deaths of non-residents: Anterior Poliomyelitis 1; Measles 1; Tuberculosis 4.

#### Miscellany.

CHANGES IN THE MEDICAL CORPS, U. S. NAVY, FOR THE THREE WEEKS ENDING AUGUST 12, 1916.

July 24.

P. A. Surgeon C. E. Strite, detached Aeronautic Station, Pensacola, Florida, to Louisiana.

P. A. Surgeon A. J. Toulon, to Aeronautic Station, Pensacola, Fla.

July 26.

Surgeon R. W. Plummer, detached *Hancock* to home, wait orders.

Asst. Surgeon James Watt, M.R.C., commissioned from June 28, 1916.

Asst. Surgeon W. W. Hawke, M.R.C., commissioned from July 5, 1916.

July 27.

Surgeon Harry Shaw, commissioned from May 28, 1915.

Asst. Surgeon R. M. Little, M.R.C., to Navy Recruiting Station, Peoria, Illinois.

FROM COMMANDER-IN-CHIEF, ASIATIC FLEET,  
SHANGHAI, CHINA.

August 2.

P. A. Surgeon D. C. Walton, detached Naval Hospital, Canacao, P. I., to Wilmington.

Asst. Surgeon L. H. Buddis, detached *Elcano* to Naval Hospital, Canacao, P. I.

Asst. Surgeon Talmadge Wilson, detached *Wilming-*ton to *Elcano*.

August 5.

Asst. Surgeon W. J. Rogers, detached Marine Barracks, Pensacola, Florida.

August 8.

Surgeon J. C. Pryor, detached Naval Hospital, Annapolis, Md., to home and wait orders.

#### NOTICES.

NEW YORK AND NEW ENGLAND ASSOCIATION OF RAILWAY SURGEONS.—The twenty-sixth annual session of the New York and New England Association of Railway Surgeons will be held at the Hotel McAlpin, New York City, on Wednesday, Oct. 18, 1916. A very interesting and attractive program has been arranged. Dr. William S. Bainbridge will deliver the "Address in Surgery," on the cancer problem. Railway surgeons, attorneys and officials and all members of the medical profession are cordially invited to attend.

DR. D. H. LAKE,  
President,  
Kingston, Pa.

DR. GEORGE CHAFFEE,  
Corresponding Secretary,  
Little Meadows, Pa.

**ARMY MEDICAL CORPS EXAMINATIONS.** The Surgeon-General of the Army announces that preliminary examinations for appointment of First Lieutenants in the Army Medical Corps will be held on September 5, 1916, at points to be hereafter designated.

Full information concerning these examinations can be procured upon application to the Surgeon-General, U. S. Army, Washington, D. C. The essential requirements to secure an appointment are that the applicant shall be a citizen of the United States, shall be between 22 and 32 years of age, a graduate of a medical school legally authorized to confer the degree of Doctor of Medicine, shall be of good moral character and habits, and shall have had at least one year's hospital training, and shall have been continuously throughout the competition in good standing. The examination will be held before boards which can be composed of three members, one given to specialties from each of the following:

ceived, in order to lessen the travelling expenses of applicants as much as possible.

In order to perfect all necessary arrangements for the examinations, applications should be forwarded at once to the Adjutant General of the Army. There are at present over two hundred vacancies in the Medical Corps of the Army.

**EXAMINATION FOR NAVY MEDICAL CORPS.**—The next examination for appointment in the Medical Corps of the Navy will be held on or about October 23, 1916, at Washington, D. C.; Boston, Mass.; New York, N. Y.; Philadelphia, Pa.; Norfolk, Va.; Charleston, S. C.; Great Lakes (Chicago), Ill.; Mare Island, Cal.; and Puget Sound, Wash.

Applicants must be citizens of the United States and must submit satisfactory evidence of preliminary education and medical education.

The first stage of the examination is for appointment as assistant surgeon in the Medical Reserve Corps, and embraces the following subjects: (a) anatomy, (b) physiology, (c) materia medica and therapeutics, (d) general medicine, (e) general surgery, (f) obstetrics.

The successful candidate then attends the course of instruction at the Naval Medical School. During this course, he receives a salary of \$2,000 per annum, with allowances for quarters, heat and light, and at the end of the course, if he successfully passes an examination in the subjects taught in the school, he is commissioned an assistant surgeon in the Navy to fill a vacancy.

Full information with regard to the physical and professional examinations, with instructions how to submit formal application, may be obtained by addressing the Surgeon-General of the Navy, Navy Department, Washington, D.C.

W. C. BRAISTED,  
*Surgeon-General, U. S. Navy.*

#### APPOINTMENT.

DR. HERBERT R. BROWN has resigned from the position of Assistant Director of the Massachusetts State Department of Health to accept an appointment as pathologist at the Rochester Homeopathic Hospital at Rochester, N. Y., the change becoming effective Sept. 1, 1916.

#### RECENT DEATHS.

DR. ROSCOE SMITH, a graduate of Harvard Medical School in 1870, and a veteran of the Civil War, died at his home in Auburn, Me., July 8, aged 79 years.

DR. THOMAS A. KENEFFICK, of New York, who died on Aug. 1, at Lawrence, Mass., was born at that city in 1840. He received the degree of M.D. in 1885 from the New York College of Physicians and Surgeons, and since that time had practised his profession in New York City and at Newport, R. I. He was a member of the American Medical Association and the New York Academy of Medicine.

DR. FRANK HAMMET HOLT, superintendent of the Michael Reese Hospital, Chicago, died in that institution, of nephritis, August 3, 1916, aged 47 years. He was a graduate of the Massachusetts College of Pharmacy in 1895 and of the Harvard Medical School in 1899, then serving as house officer at the Boston City Hospital. There he was assistant superintendent from 1904 until April 15, 1915, when he went to Chicago. He was a Fellow of the Massachusetts Medical Society and of the American Medical Association.

DR. WENTWORTH LARRABEE HAYES, of Cambridge, died at South Yarmouth, August 13, 1916, of pneu-

monia, aged 39 years. He was a native of Gardner, Me., and a graduate of Bowdoin College and of the Tufts College Medical School, the latter in 1900. He was a medical inspector of schools and a Fellow of the Massachusetts Medical Society. He is survived by his widow and two sons.

DR. JOSEPH LOGUE LOCKARY, of Roxbury, died at St. Stephen, N. B., August 13, aged 45 years. He was a graduate of McGill University Medical Department in 1897 when he settled in Roxbury, joining the Massachusetts Medical Society in the following year, and had practised there since. He was a member of the Catholic Order of Foresters and of the Knights of Columbus. His wife died about five years ago, and he is survived by a young son and by five brothers and four sisters.

DR. EDWARD L. ESTABROOK, of Minneapolis, died at the Corey Hill Hospital, Brookline, Mass., August 20, where he was taken when attacked with a sudden illness while spending a vacation in the East.

He was born in Camden, Me., July 13, 1845, and in early life served as a midshipman and later as a second lieutenant in the Civil War. He was on the *Kearsarge* at the time of its engagement with the *Alabama*. After the war he studied medicine at the University of New York, in Vienna and in Hamburg. While abroad he married Caroline Benedict of New York. He returned and settled in Minneapolis, where he remained in active practice until his death. He was a member of the Loyal Legion, the G. A. R., the Sons of the Revolution, the Masons and the Odd Fellows. He is survived by one son, Joseph Estabrook of Minneapolis.

DR. ISADOR LETT, a prominent dental surgeon, died at his home, 340 Harvard Street, Brookline, Mass., Aug. 20, after an illness of six months. Dr. Lett, the son of Michael and Hannah (Hyneman) Lett, was born in New York City 41 years ago. When a child, he moved to Philadelphia with his parents and was educated in the schools of that city. He became interested in dentistry and entered the Philadelphia Dental College, graduating from that institution. He established offices in Philadelphia and held a large practice. He came to Boston about 18 years ago and had since practised in that city.

He was considered an authority on dental surgery and was an active member of numerous dental societies and an officer of Mt. Sinai Hospital. He is survived by his widow, three children, his mother and one brother.

DR. WILLIAM H. BAKER, who died on Aug. 22, at Lynn, Mass., was born in West Chester, Pa., on June 7, 1844. He served in both the army and the navy during the Civil War, and for a decade after its close. He settled in the practice of his profession at Lynn in 1875. He was for many years president of the Board of United States Examining Surgeons, and was Surgeon-General of the Massachusetts Department, G. A. R.

DR. THOMAS POWELL, who died recently at Los Angeles, Calif., was born in Tennessee, in 1837. He received the degree of M.D. from New York Medical College in 1858, and had practised his profession in Kentucky, Indiana, and California.

DR. BENJAMIN FAGNANT, a well-known French physician of Springfield, died at his home, Aug. 19, 1916, after a three-months' illness. He was born in Canada, in 1871, and was educated at Laval College, Montreal, but had been a resident of Springfield for the past 45 years, where he had been in practice practically all that period. He is survived by his widow and a son.

#### SOME THEORETICAL CONSIDERATIONS ON THE PRESENT STATUS OF ROENTGEN THERAPY.\*

By JOSEPH SHOHAN, M.D., BOSTON,

*Roentgenologist, Psychopathic Hospital and Rufus S. Frost General Hospital.*

WHEN we stop to consider the various contradictory effects of roentgen rays on living tissues, we realize at once the many difficulties—almost insurmountable difficulties—that we were bound to encounter when we attempted to make use of the rays in combating disease. Indeed, we are not at all surprised that so little progress has been made in roentgen therapy; rather that so much has been accomplished under such difficulties.

In the roentgen ray we certainly have an exceedingly paradoxical energy. It is claimed for it that it will cure cancer, and yet before anyone ever suspected that such beneficial properties resided in that ray, we learned that roentgen rays generated cancerous growth.

On the one hand, the roentgen rays excite epithelial growth, while on the other, they destroy embryonic tissue. On the one hand, they increase metabolism and raise the resistance of the organism, while on the other, they attack the leucocytes and hinder growth.

Whoever has had the misfortune to have a roentgen burn will testify to the fact that the pain caused by it is most excruciating. In fact,

few pathologic conditions are known to cause such intense suffering. Yet roentgen rays, judiciously applied, are perhaps one of our best anodynes. Many a sufferer from some form of neuralgia, pruritus, arthritis, arthritis deformans, or similar painful condition, has been spared many a sleepless night by the use of roentgen rays.

No doubt, as a result of the contradictory effects of the roentgen rays, contradictory estimates and views of them have gained a foothold among the general public, as well as in the medical world.

There are those who behold in these rays the long-sought-for panacea of all the ills human flesh is heir to, and those who regard the rays as a new, insidious foe of mankind.

Which of these two diametrically opposed views is the correct one? They are both right and both wrong.

The epoch-making discovery of that renowned Wuerzburg professor has certainly claimed its full quota of victims, not as many among the general public as among the members of the medical profession, the undaunted followers of Roentgen. But for every victim it has claimed, it has brought relief from pain and cure from disease to hundreds and thousands the world over.

In the development of the application of the roentgen rays in medicine, accident played a not inconsiderable rôle. The old adage that "necessity is the mother of invention" does not tell the whole story. It seems to me that if necessity is the mother then accident must surely be the father. At any rate, in the case of roentgen rays, accident played the more prominent rôle.

\* Read before the South Boston Medical Society, February 7, 1916.

spicuous rôle. For it was by sheer accident that Roentgen discovered these mysterious rays, and again, it was by sheer accident that the attention of the medical world was called to the possibility of combating human suffering with them.

One day when Roentgen found—to his great surprise—that the rays from his tube penetrated opaque bodies, the significance of the use of these rays to the surgeon in cases of fracture became immediately apparent. As was to be expected, such was the first practical use of the rays.

Of course, the generating apparatus, as well as the tube, was necessarily crude and primitive, and as a result long exposures were necessary to radiograph any desired part. These long exposures of soft rays (rays coming from a tube that was not very highly evacuated) were not long in producing results,—results that were not sought for and often not desired, but results that, nevertheless, laid the foundation for modern roentgen therapy.

It was Leopold Freund of Vienna who, in 1896, a short twelve months after Roentgen's epoch-making discovery, happened to read in a local daily that someone who was working with roentgen rays a good deal suffered from dermatitis and falling out of the hair. Shortly after he also read an article by W. Mareuse, in which was related a similar experience. Freund was then moved to try this new agent to remove a hairy naevus. The success of this experiment gave roentgen therapy its first impulse.

A year later, we find Kuemmel, at the Congress of German Surgeons, reporting a case of lupus vulgaris successfully treated by means of these wonderful rays. Schiff, Hahn, Ehrman, Kienboeck, Holzknecht, and a host of others followed with the favorable reports of their experiences in the application of the roentgen rays in a number of skin lesions. Sjoergsen in cases of epithelioma.

A new era was opening for suffering humanity, for a new weapon was placed in the hands of the disciples of Esculapius.

With the wonted enthusiasm of the new convert, medical men the world over took up the study and practice of this new "ology," roentgenology. Some of these early enthusiasts have long since paid the penalty of their devotion and are sleeping peacefully their eternal sleep—all but forgotten. Others more fortunate are still with us, unlaurelled and undecorated heroes in the army of peace for the cause of suffering humanity.

We in Boston should take just pride in the fact that our city has produced one of these early pioneers in the person of Dr. Francis Williams. His contributions to the study of roentgenology form veritable landmarks and are, I hope, fully appreciated.

While the reports of wonderful cures and burning disappointments—burning in more than one sense—came thick and fast, the paramount

question that agitated most of these workers was—how do these rays produce all these wonderful results? What was the *modus operandi*?

Fortunately, the medical man, with his traditional instinct for empiricism, did not stop too long in search of theories. He knew too well that the explanations of today are, alas, too often the fallacies of tomorrow. Nevertheless, in this age of rationalism, it was, of course, necessary to have a rational explanation for a basis of "rational therapy," as it is too often misleadingly termed. The rational explanations came in great profusion, needless to add, only to cause a good deal of confusion.

It was the electricity in the current with some; with others the ionization, the magnetic effect, the psychic effect. And the discussion waxed hot.

But before the roentgen therapist could find and give a satisfactory answer, the roentgen-physicist had to tell him first, what were those rays—what were their physical properties?

When Professor Roentgen in 1895 discovered that new type of radiation he himself suggested for it the term x-ray, doubtless not only for want of a more comprehensive term, but also because that new phenomenon presented to him an unknown quantity in more than one sense of the word.

Were these radiations solid particles, or were they waves? If waves, what kind—transverse like sound waves, or longitudinal like light waves? These points and a host of others kept the physicists in agitation for quite some time.

Today, the most important points are settled beyond dispute. We know that the roentgen rays are longitudinal electro-magnetic waves that can be deflected and refracted, and resemble the waves of gamma rays of radium, of ultra-violet rays, heat waves, the waves that transmit our wireless messages, and other light waves, and differ from them in one respect only, namely, the length of the wave. The length of the wave is the determining factor of its physical characteristics.

As R. Pohl aptly puts it, "The roentgen rays that emanate from our discharge tube or the roentgen rays that are emitted by radio-active substances known as gamma rays, are principally nothing else but light, and all that we know about light applies to these rays, with very few exceptions."

But while the physicists were pursuing relentlessly their war on nature in their efforts to wrest from her the secrets of the wonderful rays, the therapist was not sitting idly by.

As mentioned before, skin lesions and epithelioma were the first to arrest the attention of medical men the world over, and skin therapy was all but revolutionized.

However, roentgen therapy, unlike maligned beauty, was not to be merely skin deep.

About the year 1903 Nicolas Senn conceived the idea of subjecting a leukemia patient to

roentgen rays. He radiated the spleen of his patient, and to his great delight noticed a retrogression of the enlarged spleen and a general improvement in the condition of his patient. The report of his experiences in the *New York Medical Journal* of April, 1903, was at once taken up abroad with great enthusiasm and gave impetus to the classic researches on blood by Heineke, Linser and Helber, Jagie, and a host of others.

The year 1903 was destined to be a red-letter year in the annals of roentgen therapy. It was in 1903 that Albers Schoenberg of Hamburg, that martyr to the advancement of roentgenology, made his epoch-making observation of the phenomenon of sterility induced by roentgen rays. He made his first observations experimentally on rabbits and guinea-pigs. A year later Philipp reported the first two cases of sterility in human subjects.

This classic work of that master-mind, Albers Schoenberg, laid the foundation for our modern deep roentgen therapy, with all that it implies, and gave a new impetus to the roentgen therapist and renewed interest in the most absorbing questions,—how these rays influence living tissues and by what *modus operandi* we effect our cures and our injuries. For, as roentgen therapy assumed greater and yet greater proportions, the number of victims multiplied.

That it was not a mere chemical or physico-chemical reaction between the rays and living tissues soon became evident.

I have already referred to Heineke's researches on the blood. He and the others showed that roentgen rays effect, at first, a short temporary rise in the white blood count followed by a drop, in which the polynuclear leucocytes suffer the most, and next to them the lymphocytes. Now, if that were a mere chemical reaction, the rays ought to affect the chemical composition of the blood *in vitro*—in the test tube. But Bergonie and Tribondeau as far back as 1908 submitted defibrinated blood to the action of the rays for as long as thirty minutes and failed to detect any change whatever. They also submitted spermatozoa to similar tests, with equally negative results. Bordier and others performed similar experiments with like results. Furthermore, it soon became apparent that different tissues, normal and pathological, under the same given conditions, react differently. We saw that the various constituents of the blood were not all affected alike: the polynuclears suffering the most, while the erythrocytes were hardly affected, even after prolonged exposures. The cells of the lymphoid tissue, of the hair papillae, and of the epithelioma readily succumb to the action of the rays, while the epithelia of the skin remain intact.

These phenomena were explained by some on the assumption of a selective action of the rays on the cells, i.e. the rays attack certain cells more vigorously than others. Others again saw in the cells themselves a variable vulnerability.

Be that as it may, it is clear now that the reaction between the cells and the rays is a bio-chemic reaction. As Dean Butcher states it, "It is not the chemical reactions of material remedies, with which we are more or less familiar, but the impact of ethereal waves on living tissues. These ethereal waves of various lengths and frequencies are the real therapeutic agents."<sup>2</sup>

But if the length of the wave, or, in other words, the hardness of the ray is of prime importance, it probably is not all-important.

Wickham, whose work on the biochemistry of radio-activity is most painstaking, states:

"Every ray that strikes a cell, no matter what the source of the ray is, exerts some influence on the cell. This reaction is the result of many and various factors. The most important ones are:

"1. The degree of the receptivity of the cell; in other words, its specific radio-sensibility.

"2. The quantity of rays absorbed in a unit of time.

"3. The specific peculiarity of the kind of rays.

"4. The time elapsed between the radiation and the histologic examination.

"5. The filtration of the rays through the tissues."<sup>3</sup>

He says further that among all these factors the radio-sensibility of the cell is of the greatest interest. He continues, "When a cell is affected by the rays it is not correct to say that the ray has a specific action on the cell. It is not a question of specificity, rather of cell sensibility, of particular receptivity. This particular receptivity is what causes a penetrating ray to go through a layer of healthy tissue without affecting it, but when it finally reaches a pathological tissue underneath, it exerts an influence there."

We see from the foregoing that Wickham ascribes to the sensibility of the cell first importance, though, of course, he also takes into consideration the hardness of the ray, that is, the wave-length.

Several attempts have been made to classify the various living tissues in accordance with their radio-active sensitiveness. The following classification of Wetterer is, no doubt, the best:

"*Normal Tissues.*—Lymphoid tissue, testicles and ovaries, facial skin on child, child's cartilage, mucous membrane, hair papillae, child's body-skin, intima of blood vessels, skin on face of adult, sweat and sebaceous glands, skin on body and head of adult, liver and kidney parenchyma, blood vessels, connective tissues, muscles, cartilage of adult, bone.

"*Pathologic Tissues.*—Leukemic and pseudo-leukemic tissue, recent patches of psoriasis, acute eczema, chronic eczema, mycosis fungoides, lymphosarcoma, acute vulgaris, old patches of psoriasis, round cell sarcoma, hypertrophic pro-

tate, hypertrophic lupus, tuberculous lymphoma, carcinoma, mycotic hair, bone tuberculosis, parenchymatous goitre, lupus planus, dry form, warts, lupus verrucosus, fibroma, myoma."<sup>4</sup>

It was left, however, to Bergonie and Tribondeau to formulate a law of the radio-sensibility of living tissue, which might be said both to generalize and express synthetically all our data on the subject of roentgen therapy. Their law reads: "The radio-sensibility of the living cell is directly proportional to:

- "1. Its reproductive power,
- "2. The duration of its karyokinetic process, and
- "3. Inversely as its morphology and specific function are definite and stable."<sup>5</sup>

The third law really is merely a corollary to the first two.

To these three laws or generalizations Beclere added a fourth one. He states that "every living cell, be it healthy or diseased, when subjected to a sufficient amount of roentgen rays, will undergo chemical reactions, the ultimate result of which is the degeneration and death of the irradiated cell."<sup>6</sup>

We see thus, that in the reaction of the rays on the living cell the quality and quantity of the rays, as well as the kind and condition of the cell, are important factors. We can thus conceive of the rays as a stimulus acting on the living cell, affecting it in proportion to its vitality and stability. The young immature cell or the one still in the process of reproduction, when bombarded by the radiations, readily succumbs; while the mature and more stable cell resists onslaught, remains uninjured, and is, furthermore, stimulated to full and stable growth. This conception clarifies many of the seemingly paradoxical actions of roentgen rays on living tissues. It becomes clear to us why the skin is more sensitive than connective tissue and muscle fiber, why the rapidly multiplying lymphoid tissue is more sensitive than the skin. The phenomenon of sterility induced by roentgen rays becomes very evident. The polynuclears in the blood stream, as might be expected, are the worst sufferers when blood is radiated. This conception should also prompt us to apply roentgen therapy in conditions hitherto untried.

When I was at the St. Georg Hospital in Hamburg last winter, I had occasion to observe a large number of wounded soldiers with suppurating wounds, which, for some reason or other, refused to close up. They usually had an abundance of granulations, and a profuse creamy discharge. I suggested roentgenizing some of these wounds. Needless to add, I did not aim at a bactericidal effect, for the dose required to attain that is much too high for therapeutic purposes. What I hoped for was, on the one hand, to strike at the polynuclear leu-

coeytes, which furnish almost all the pus cells; also at the granulation tissue, which consists of rapidly proliferating vascular endothelia and fibroblasts; and, on the other hand, to stimulate many of the more resisting fibroblasts to mature growth, and thus hasten cicatrization. My results exceeded my most sanguine expectations. A preliminary report of this work was made before the Hamburg Medical Society.

The next question that rational roentgen therapy had to answer was whether the action of the rays was purely local or systemic. In other words, is the effect of radiation merely the result of the reaction between the rays and the cells they happen to hit, or do the rays in some way exert an indirect distant influence over the entire organism? This question has more than academic interest, for were the effect a purely local one, we could never hope to accomplish anything with this new agent in our combat with malignant growths. No local agent, however promising, could ever prove successful against them, not alone because we are not at all certain that these growths are purely local phenomena, but also because in any given case of a malignant growth we have no means of ascertaining that some metastatic foci do not already exist at some distance from the given focus. No doubt, the much too common post-operative recurrences are in most cases due to remote metastatic foci. Wetterer, in discussing Ritter's negative experimental results, adds, "However, one is not justified in excluding the possibility of an indirect effect of radiation."<sup>7</sup>

F. Gudzent, in his lucid discussion of the influence of radio-active substances on the blood, says: "But the question whether this effect is a direct or indirect one is not yet settled today. However, the experimental observations that point to the contrary do not harmonize well with the common observations made by therapeutists. It is an established fact that leukemic tumors recede, even when they are not directly exposed to the action of the rays. Furthermore, as Arneht pointed out, the entire condition of the blood is greatly improved by the radiations; it undergoes a biologic alteration of function which could never be explained by the mere destruction of cells."<sup>8</sup>

Robert Knox, in his very admirable text-book, in the chapter on "Action of Radiations Upon Tissues," says: "The action of radium and x-rays upon the normal tissues and on morbid growths is . . . not purely a caustic action. In addition to the direct evidence of a local action of radiations upon the cell of a new growth and its surrounding tissues, there is reason to believe that a general effect is produced upon the whole body."<sup>9</sup> He points out the general improvement in the patient's health while under treatment, no matter what area of the body is radiated. He concludes: "The general effect may be quite as useful as the local, and if it has any value at all, it would be extremely useful to bear it in mind, because one need not then

limit the areas of exposure. After local treatment has been pushed to its limit, the treatment may be continued in other parts of the body."<sup>9</sup>—a very valuable and far-reaching suggestion.

While the experimental evidence is as yet not conclusive, the empirical evidence is overwhelming that the effect is systemic as well as local.

Of late years the post-operative radiation of all malignant cases has become almost universal in Western European clinics. The observation was soon made by many roentgen therapists that when they radiated the scar of an amputated breast, in many instances, the enlarged glands in the axilla disappeared of themselves, although never exposed to the rays. It was further observed that quite often while a patient was being treated locally for malignancy of the breast, a foul vaginal discharge from which she happened to suffer at the time was markedly improved. These and similar phenomena could be explained only on the assumption that the rays effect a systemic action.

How this is brought about is of less practical import to the therapist. I shall merely mention that three hypotheses have been advanced. The radio-vaccine hypothesis of Dean Butcher is probably the most plausible one. As opposed to this vitalistic theory, Professor Stephane Ledue proposed the mechanistic theory. Another is the so-called cannibalistic theory of Ross. I do not intend to enter here into a discussion of the merits of these different hypotheses. But I do want to call your attention to the circumstance that every time we roentgenize any given area, we thereby also radiate the entire volume of blood. Landois states that the duration of the blood circulation in a healthy human subject, with a pulse-rate of 72 per minute, is 22.5 seconds.<sup>10</sup> This being so, it follows that the entire volume of blood passes through the heart in 22.5 seconds. Were we to roentgenize the heart area with sufficiently hard rays, say a parallel spark gap of 10 inches, then the blood in the heart would receive approximately half of the skin dose. If the skin dose administered through several ports of entry were 100X, then the heart would receive about half of the skin dose, or 50X, and the entire volume of blood would receive 2.25X—quite a respectable dose, when we stop to consider that 1/13 of the whole body weight is subjected to it.

What is true of the heart must needs be true whenever we radiate any given vascular area in which the combined volume of its blood vessels is equal to the volume of blood in the heart. And this roentgenized blood makes its way freely through the entire organism, and bathes every one of its cells. Such being the case, it is difficult to conceive of the blood not exerting a greater or less indirect influence over the entire organism.

In the foregoing I have attempted to point out the theoretical difficulties which roentgen therapy met on its way, and to a certain extent

overcame. There were, however, others more immediate and more practical. The problem of dosage soon assumed formidable proportions. As soon as we found out that radiation in certain amounts proved beneficial, while in other amounts harmful, it became evident that without some means of measuring the exact amount to be given in each case, we were all at sea, and roentgen therapy was without a future. For, with too much caution, we might administer less than was necessary, and defeat our object. Nay more, we might even harm our patient with the smallness of the dose, or administer an overdose, with invariably disastrous results.

For a while the roentgen therapist certainly worked under difficulties, keeping within the safest possible bounds, and almost despairing of better days. It was then that Guido Holzknecht, the foremost of our pioneers, and himself a victim of his roentgen experiments, came to the rescue and devised his dosimeter. He was followed by Kienbeck, Sabouraud, and others with various devices. To be sure, a great deal is still to be desired in the matter of quantimetry, but Holzknecht's device was certainly a great step in the right direction.

We hear nowadays a great deal about deep-therapy. Usually we mean by that therapy in gynecology, although it really refers to the therapy of all deep-seated organs. Now deep-therapy is not conceivable without the classic researches of Perthes in the matter of filters. It was again in 1903, in that red-letter year, as I have already termed it, that Perthes called attention to the fact that it must needs be possible to increase the deep effect of radiation, when a filter of some sort, like aluminum, is interposed between the tube and the patient, thus intercepting the soft rays and permitting the hard ones to reach the patient. He added that it would be desirable to ascertain to what extent this increased effect can be induced. And he did determine it, for in the following year he published his researches, which, as Gauss and Lembke—the fathers of modern intensive therapy—say, were of fundamental significance for the development of deep-therapy.

Indeed, while it is true that in the early years roentgen therapy was confined merely to skin disorders and other superficial lesions because of the lack of proper appliances, lack of dosimeter, lack of filter, and even lack of appropriate tubes, today the conditions are altogether changed. In this connection let me state that the perfected tube of Dr. Coolidge has improved the armamentarium of the roentgen therapist a hundredfold.

Today, deep as well as superficial roentgen therapy is no longer an experiment but an established fact.

We have seen how the theoretical ground has been cleared from the physicist as well as from the biochemical aspects, the practical and technical difficulties have been overcome, and that the purely empirical fact, the efficacy of the radiation

tory therapists has grown so fast that it forms a vast literature of its own.

It is not my intention to-night to enter into a discussion of skin therapy; the roentgen ray as a therapeutic agent in dermatology has long proved its worth and is established as the remedy par excellence for many skin diseases, especially those of a more chronic nature. Slowly but surely roentgen therapy is widening its scope in internal medicine, surgery, and last but not least, gynecology.

As far back as 1902, fourteen years ago, Dr. Francis Williams treated the first case of Basedow in his roentgen laboratory. He was followed by the late Carl Beck, and a host of others. It was at that memorable meeting of the medical society of Vienna, where Holzkecht, then a comparatively young docent, made his brilliant retort to the well-known Professor v. Eiselsberg. Professor Eiselsberg, one of Austria's foremost surgeons, discredited roentgen therapy in Basedow, and went so far as to accuse it of causing adhesions and making any subsequent operation more difficult. Holzkecht demonstrated a series of cases and remarked, "You see, gentlemen, that the roentgen therapy is not at all 'immaterial,' and is not effective 'only on rare occasions,' as Professor von Eiselsberg would have you believe, rather are the good results frequent, and at times brilliant." In defense of roentgen therapy he quotes from a letter that he received from Carl Beck, in which the latter had stated, "In Basedow my results in most cases are downright wonderful; in smaller struma I had only one failure out of 38 cases, five of these were partly successful. The result in the other 32 cases—90%—was just splendid."<sup>11</sup>

Belot reported recently 30 cases of Basedow, out of which only five showed no improvement, and those were not true Basedow's. He quotes Ledaux-Lebard, who said, when speaking of roentgen therapy in Basedow, "everything goes along in the favorable cases as though under the influence of the roentgen rays, the hyperthyroidism is gradually substituted by normal secretions, or as though the very products of the glands gradually approached the normal."<sup>12</sup>

I recollect three cases that I had under treatment while I was assistant to Albers Schoenberg. One was a post-operative case in which one lobe was removed and the other roentgenized. Beck was the first to suggest this combined method. I could see constant improvement in the three cases, both subjectively and objectively, while I had them under my observation.

I have mentioned before Senn's classic case of leukemia. The medical literature of to-day is full of hundreds, possibly thousands, of cases reported, some with more, others with less favorable results. Beclere recently reported 110 cases, some of those observed since 1904. In talking of the lymphatic leukemia (12 cases) he says that all these cases have been influenced

by the radiation quite remarkably. The first sign of improvement was the return of the patient's strength; along with the diminution of the spleen and lymph nodules came the disappearance of the insomnia, the return of the appetite, and the increase in weight.

He had ninety-three cases of myeloid leukemia. Of these he says, "The consequence of our treatment was that up to date we did not have any case that was not favorably influenced by it."<sup>13</sup>

The treatment of phthises is still *sub judice*, but the experimental and clinical work of De la Camp and of L. Kueperle are highly interesting and worthy of attention.

For a while I had a patient under treatment—a far gone case—nevertheless, I noticed a marked diminution of sputum, and, what was more interesting, she gained a pound during the first week of treatment, the first pound she had gained in many months.

I spoke of the roentgen rays as an anodyne in neuralgia, sciatica, pruritus, arthritis, and the like. I recall one interesting incident that occurred while I was in Hamburg. One morning I overheard a conversation between two patients in the treatment room. One was saying to the other, "Say, why don't you ask him, he will do it?" As I approached they said no more. When I inquired of one what it was all about, she informed me that she had merely suggested to Frau So-and-So to ask me to treat her sciatica, which had continued bad for the past few days. Frau So-and-So was being treated for mediastinal sarcoma post-operative. I asked her how she knew of the treatment of sciatica by roentgen rays, and whether she believed that the rays were a cure-all. "Oh, no," was the frank answer, "but my sciatica does not trouble me any since I am being treated." Now this patient was being treated for a good-sized fibroid, and received roentgenizations posteriorly as well as anteriorly. It was new to me, and I told my chief what I had learned from my patients. He laughed and said that he knew that such cases were reported, although he had never treated any knowingly.

As a matter of fact the utilization of the roentgen rays as an anodyne dates as far back as 1897, two years after the discovery of the rays. Gocht reports a case of long-standing trigeminal neuralgia. The patient came to him for surgical aid, for his suffering was intense and could be relieved only by large doses of morphine. Instead of resorting to an operation, Gocht tried, by way of experiment, to expose his patient to the roentgen rays. Much to the surprise and delight of both doctor and patient, after the second day of treatment the patient was free from pain and could get along without morphine.<sup>14</sup>

Numerous similar results have been reported since then, both in this country and in Europe.

Engelken reports a very striking case. A man,

48 years old, suffering from right-sided neuralgia of a branch of the trifacial nerve, was operated on, and the offending nerve was removed without any relief to the sufferer. After four radiations of fifteen minutes, the patient was free from pain. There was a relapse four weeks later, which yielded to treatment in a similar manner.<sup>15</sup>

Tuberculous lymphadenitis forms a particularly grateful field for the roentgen therapist. These cases, judiciously selected, yield to treatment almost invariably. In view of the good results reported by all observers and amply sustained by my own experience in a number of cases, I feel that it is an injustice to disfigure so many faces, when by means of roentgenization they could well be left unmarred. At least, it seems to me that every victim of tuberculous glands has a right to demand from us that we give him a chance by means of roentgen therapy to escape the scarring of the surgeon's scalpel.

Roentgenotherapy in gynecology is a very broad subject, and I can not stop to discuss it in detail now. In European clinics, at least, it is too well established to need any argument in its favor. Out of the Freiburg clinic, Gauss and Lembecke reported two hundred and five cases. These were treated between 1908 and 1912, a period of four years, and comprise cases of myomata and various forms of metropathies. The former class of patients form by far the largest number. The object of the treatment in all these cases was to produce amenorrhea, and where a tumor was present, to reduce it in size. Both these objects were attained in practically all the cases. The results were particularly brilliant in the last two series of cases after they had perfected their technic, which enabled them to administer large doses. In their summary they go so far as to declare, "We are now so certain of our technic that we can cure our patients in a short time to stay cured, no matter what their age and the size of the tumor may be."<sup>16</sup>

Beclere recently reported sixty-six gynecologic cases treated by him with roentgen rays. Six of these patients were treated for bleeding only—no tumors of any kind could be made out. Two of these even had a subnormal uterus. All the other cases showed a palpable tumor, and complained of irregular uterine hemorrhages. He states that "the attained results in all those cases were very favorable." He adds, "in the treatment of the uterine myoma by roentgen rays, more importance is to be attached to the direct action of the rays on the tumor muscle itself than on its indirect action through their influence on the ovaries."<sup>17</sup>

My personal observations in the laboratory of Albers Schoenberg bear out fully the statement of Gauss and Lembecke. A large number of patients of various ages were treated there for various conditions, such as myoma, fibroma, climacteric disturbances, and metropathies of various kinds. I recall a very striking case of

a young woman of 34, who came to us almost in a state of collapse from dissanguination. She suffered from anemic headaches, cardiac palpitation, insomnia, and general debility. She responded to treatment remarkably well. I left the laboratory while she was still under treatment, but her uterine hemorrhages had almost ceased.

Such and similar observations lead me to conclude that in all cases of fibromata and myomata the very least we should do, in justice to ourselves and to our patient, is to let her choose between surgical therapy and roentgen therapy; for where there are no indications to the contrary, the latter is at least as efficient as the former, without its accompanying risk.

F. Ebler, in discussing roentgen therapy in gynecology, remarks, "The time is not far distant when no gynecologist will be considered progressive who will not use roentgen rays in his daily practice."<sup>18</sup>

Before I close, I wish to say a few words on the present status of roentgen therapy in malignant cases.

If the biochemical theories which I have briefly discussed before mean anything at all—and they surely mean a great deal if the generalizations as laid down by Bergoni and Tribondeau synthesize the facts—then there is ample reason to hope that roentgen therapy has within itself the promise of a better day for the sufferers from malignant diseases.

Kroenig of Freiburg and his followers, already a school by themselves, some of whom I know to have come to seoff and stayed to pray, have already placed their knives back in their sheaths and have replaced them with the roentgen tube. I am not quite ready to follow their lead yet, but for the glory of surgery and in justice to humanity, let at least every post-operative case be judiciously roentgenized. We shall surely have fewer recurrences then.

The pioneer work has long been done. It is for us to do the rest.

### SOME EFFICIENCY PROBLEMS IN COUNTRY MEDICAL PRACTICE.\*

By FRANK H. WASHBURN, M.D., HOLMEN, MASS.

Not many decades ago an individual afflicted with disease often determined his own prognosis in the choice of his physician; *i.e.* results, as far as medical influence affected them, depended upon the skill and judgment of his doctor, who worked, usually single-handed, with the resources at his command, largely his personal, mental and material equipment.

Since the advent of the microscope, the arrival of the influence of biology, of animal experimentation, the entrance of the various branches of science into diagnosis, the increase of specialization, the development of instruments of precision, the organization of public health forces, and finally the development of team work, not only in surgery but in the diagnosis and the therapeutics of internal medicine, there has developed in every community what may be termed its "medical machinery" and upon the efficiency or inefficiency of this structure depends the prognosis of an individual case rather than upon any personage. To be sure, the keenness and conscience of the practitioner consulted is and probably ever will be a factor of great importance.

It would be a waste of time to enumerate all the component parts of this health promotion group, or this "machine," which exists in every municipality; however, it must be apparent that the smaller the community the less elaborate, if not less efficient, must this be.

It is of the development of the efficiency of this "medical machine" in small communities, rather than that of individual effectiveness, we wish to speak; and although we are all factors, or parts, but limited discussion of the individual as such will be entered into.

That the stigma of comparative inefficiency to some degree occasionally attaches to the country practitioner may be asserted without fear of successful contradiction. Whether the brand be just or unjust, or whether his actual shortcomings be fancied or real, does not alter this fact. In support of this statement the essayist recalls the fact that when he made his debut in his present village location, one of his greatest assets was the prevalent knowledge that he had practised in Boston. The fact that he had been a mere struggler there, and for but a brief period, mattered not. Conversely, he recalls that being a country doctor became somewhat of a handicap in his Worcester practice a few years ago.

A short time since there appeared in the *Journal of the American Medical Association* an article on the "Conduct of Normal Labor."

\* Read before the Worcester District Medical Society, April 12, 1916.

which probably would have been a timely essay had it been published a quarter of a century ago. Many protests were received by the editor, who explained its appearance by stating that it was intended for the men who practise in the country, away from the great medical centres. It was gratifying to note that a deluge of protests emanating from country doctors all over the United States were poured in upon the editor of the journal, indicating that some, at least, do not grease their hands with petrolatum before inserting them into the uterine cavity, and that rubber gloves are not unknown even in the backwoods.

Before we who practise in the suburban and rural districts refute this charge of comparative inefficiency, let us analyze, as far as we may, our conditions, and by a process of introspection examine the motives that may have lodged in our conjunctivae.

We trust it may be granted that the men who enter upon country practice as they leave the medical school and hospital are, on the average, practically as well equipped as they who begin their professional work in the great cities.

Even this is sometimes controverted. In the recent State Board number of the *Journal of the American Medical Association*, Gordon Wilson, in an article on "Medical Education with Reference to Rural Communities," endeavors to show that college-bred men graduating from high-grade medical schools avoid rural communities, and suggests two grades of medical schools, evidently intending the class of schools having low-grade requirements to furnish men for country practice. No one doubts that certain men train with definite hospital appointments and teaching positions in view, and finish their medical training equipped to the superlative degree. Such men, of course, do not even consider a country location,—however, they form but an exceedingly small percentage of even the thoroughly trained. To the rank and file, we feel that both city and country appeal, regardless of preparation.

The desire to gain an active practice quickly, the love of the open and the demands of broken health are among the most frequent incentives to the young physician's choice of a country practice. As he becomes established, he learns that his ever-increasing activities bring him in contact with an endless variety of humanity and of social phases; and as varied morbid psychic and physical conditions. He is thrown upon his own resources, often where his city brother may share his responsibilities with his neighboring colleagues.

What a school of self-reliance this should be, and is; but there is another phase. One here finds himself doing one of two things,—either endeavoring to meet, unaided, many medical problems, whether involving the eye and ear, or the genito-urinary system, the female reproductive organs, the digestive tract, or "what

not"; or he is directing his clientele to the various specialists of varied eminence, practising in their restricted fields in the most accessible large centre.

The first is inclined to spread himself out thinner and thinner as the demands upon him increase, until he is brought face to face with the problem of combating the tendency to superficial attention to his cases, and likewise superficial knowledge. The second tends to lack of confidence and self-reliance, and to final deterioration into a human guideboard.

These are but propensities, for it is apparent that only a portion become superficial thinkers, or acquire justification to have "dirigo" placed upon their tombstones.

The doctor in the less populated district has few colleagues about him, and too often he considers them as competitors. The prospect, or rather fear, that he may lose patients deters him from leaving home for post-graduate study and recreation, thus the tendency to become "stale," as we say, with the resulting sluggish cerebration and mental astigmatism and myopia.

The country doctor pays a little more for every domestic commodity—his groceries, meats, coal, electric lights, etc.—than does his city brother. His area of travel is greater, and likewise the expense in time and money in reaching his cases. His rent, if he does not own his home, may be a trifle less. That he gets less of the modern conveniences is not relevant. He charges fees that are less by 30 to 40% than those of the urban doctor. He gives away throughout each year hundreds of dollars' worth of drugs. All these are mentioned as retarding the growth of his armamentarium, and especially of his library,—his "sine qua non" as regards mental improvement.

Because of the inaccessibility of hospitals, his emergencies are often attended without the assistance of competent nursing, and his charity cases are, necessarily, usually attended without the help of trained assistance of any kind, however urgent may be the need; thus another tendency to inferior results.

He is remote from clinics, the meeting-places of his societies, libraries, and that which is fully as important,—the proximity to enthusiastic men with whom he may discuss his cases and talk shop.

Now what should concern the individual rural medical practitioner himself is the question as to whether he has done his part in maintaining and enhancing his personal efficiency, and that of the health promotion and conservation forces potential in his community.

Critical introspection long ago forced upon the writer the secret acknowledgment that the "medical machine" of his neighborhood, of which he was a part, needed much adjusting to meet its normal efficiency and output. A more or less definite plan was outlined, and it occurs

to us that, while as yet little has been achieved, the incipient efforts of my colleagues and myself to better medical results in Holden—a town of less than 2500 permanent residents—might be of interest, as illustrations in this discussion, to others similarly located, and that mutually beneficial suggestions might result.

First, and most important, the acquisition of personal knowledge must be an important part of any plan of this kind, and feeling that our position, in this respect, contains nothing to exhibit, we merely leave this as a general statement. No man should be satisfied with what he can "dig out" from his own experience and the literature at his command, however valuable, but should get into personal touch with the work of others. Whether one's interest lies in the line of surgery or internal medicine, post-graduate study, visits to the master teachers and their clinics should be aimed at. The aetna achievement is possible only through expenditure of time and money. If one exists upon the ordinary income from country practice, this is difficult. This leads us to the consideration of the commercial phase of practice, a subject we are reluctant to touch, yet, as long as we must exist under a system of profit, just as does the tradesman, we must face it. In Holden we have gradually increased our fees. That gradual increase will stop only when we are getting material return for our work equal to that of city practitioners, and can support our families somewhere near equally with our neighbors, who are tradesmen, clerks and mechanics. To those who are deferring raising their fees because neighboring physicians are not ready to come in, we can say from personal experience that only a negligible amount of practice is lost, and one's condition is but improved by independent action.

To our confrères of the towns, we wish to say that, although we have discussed what might be termed the etiological phase of lack of efficiency, we have intended to refrain from actual admission, but are trying to view what others think of us.

Now people expect what they pay for, and while we offer our services for three-fourths of the value placed upon theirs by certain others, can we but expect the public to judge us by any other than its usual standard of values? We trust that no one will misunderstand our position, especially to conclude that we stand for grasping.

While we advocate a greater income for our services, or rather, while necessity demands it in the interest of efficiency, we must ever keep in mind the ideals of our profession, and the fact that primarily our object is a humane one, and that our instructions should be given as freely to the poor as to the rich, and that we should be ready to make sacrifices. If a more efficient service should be rendered to the community, we are ready to do it.

Briefly, we state our plan for the future.

sion; our incentives, education, science and humanity. But incidentally our very existence, and professional improvement as well, demands a certain amount of "cold cash." I know of no desirable alternative to charging those who are able to pay, a fee that will compensate for our altruism to the extent of, at least, ensuring us an income by means of which we may live honestly and at the same time keep pace with current professional advances.

No plan of mutual improvement can meet with its maximum success without neighborly association among members of the local profession, and the absolute quashing of professional jealousy. We have found that, whereas formerly we considered the employment of a "locum tenens," during temporary absence from our practice, necessary, it has proven no less profitable merely to turn the work over to our colleagues, permitting the patients to make the choice. Enhancing this friendly state, and to the improvement of actual results, we have found our neighbors better qualified for certain work than ourselves; thus one takes an interest in the neuroses and in electro-therapeutics, and as all such special cases in a small town are but enough to support one good equipment, the cases needing special thought are referred to him; another acquires supremacy in skill in anesthetizing, and should have that practice. In this way we may divide the work to our mutual relief, as well as benefit to the patient. "Creeping into the lives of men everywhere," said Elbert Hubbard, "is the thought that co-operation is better than competition. We need each other."

The practitioners of three or four contiguous small towns may unite in a medical club, with splendid results. The free discussion at these less formal clubs often creates an interest among the members which tends to the exchange of much practical knowledge. The long distances necessarily traveled by the members who attend is, since the automobile has become the universal mode of travel for the doctor, less of an obstacle. We recall many profitable evenings spent with the Rutland Clinical Club.

We have no intention of discussing the pros and cons of drug dispensing, but wish to say that unquestionably it is an impossibility for one to have at hand all the remedies desirable for modern therapeutics.

A practitioner whose only source of immediate supply is his own drug stock is daily forced to make undesirable substitutions. The coming of a *reliable* pharmacy to any town where none has previously existed should, in the interest of therapeutic results, meet the approval and welcome of its doctors.

When some of the local societies began to talk of a visiting nurse for Holden its physicians approved. The visiting nurse is the solution of many of our efficiency problems in rural practice. She brings asepsis to the mill tenement

obstetric case; she ensures the pursuit of a hygienic regimen in the home-treated tuberculous case; she may follow up the suggestions of the school physician and make his work bring results, and she may be an invaluable assistant to the board of health. Our society has disseminated knowledge by lectures at its meetings upon "Rural Hygiene," "Facts About Cancer," "Oral Prophylaxis," "Common Sense in Contagious Diseases," "Tuberculosis," "Prenatal Care," etc., and hopes to enlarge its scope in the future.

A few years ago some of the public-spirited men of Holden met with its physicians, and discussed the practicability of a small public hospital. At that time it appeared evident that the money could have been raised for the building and equipment, but none of us felt that we could prophesy a proper maintenance in so small a town without an available fund of some kind. Subsequent experience has taught us that it could have been accomplished. While that scheme was suspended, the need of hospital advantages for our patients continued, resulting in the opening, something over a year ago, of the Holden Cottage Hospital, which is under private control, but attempts the functions of a public hospital. This institution is a small nursing home, modest in its outlay, consisting of a 10-room house, equipped with accommodations for five or six patients, and the necessary appliances for the care of medical, surgical, and obstetrical cases.

The operating room, while small, is supplied with good north and west light in day, and ample electric illumination by night. The sterilizing apparatus is, at present, of the non-pressure type, requiring considerable time and attention in its operation, but efficient for perfect asepsis. Essentials consistent with modest outlay have been aimed at, and elaborate appliances have not been possible.

The hospital is owned and conducted by a lady—not a trained nurse—and her husband. One trained nurse is constantly in charge; others are employed as occasion permits. The average number of nurses the first year was about two. At operations requiring an extra nurse, the visiting nurse is employed. In this way we are enabled to maintain something of a team. The privileges of the hospital are open to any physician in the community, or any other practitioner of known reliability.

The charges for board and nursing are from \$15 to \$25 per week, with an extra fee for use of the surgery, dressings, etc.

The following brief abstract of the first year's report is submitted:

Number of admissions.....	74
Male .....	35
Female .....	39
Residences:	
Holden .....	44
Worcester .....	15
Other cities and towns.....	15

The cases for treatment were:

Medical .....	17
Surgical .....	48
Medical and surgical .....	2
Obstetrical .....	7

Of the 74 cases 5 died.

Besides these, there were 5 newborn with one still-birth.

The causes of death were:

Medical—uremia .....	2
Acute colitis .....	1
Chronic asthmatic bronchitis .....	1
Surgical—acute intestinal obstruction .....	1

This death followed operation upon strangulated femoral hernia in an old lady of 75 who had suffered from an attack of uremia due to chronic Bright's disease.

Operations under general anesthesia .....	40
Operations under local anesthesia .....	4
Operations without anesthesia .....	4
Average number of patients per day .....	2 53/73
Least 0. Most 7. Average stay .....	834/37 days

While it may be outside the intended scope of this paper to describe details of the surgical work, I desire to allude briefly to two or three of the most prominent features in routine procedure. My reason for this results from a conference, at about the time of starting the project, with a member of our society who is a prominent surgeon and a valued personal friend, from whose conversation I inferred there might be doubt as to whether some of the refinements of modern technic could be accomplished under conditions which must obtain in so small an institution.

While any visitor or consultant uses methods to his liking, ordinarily we confine our aseptic technic to the simplest. Iodine preparation of dry surfaces, or thorough cleansing of moist surfaces with soap and water followed by ablutions of 70% alcohol, constitutes the whole scheme of skin preparation in the patient. Soap and water, boiled rubber gloves and 70% alcohol suffice for the operator's hands. As few drapings as necessary to cover the field properly, and as few assistants as consistent with reasonable needs, are used.

While strict asepsis is the "sine qua non," next in importance we consider the *anesthesia*.

If the patient is in hand for a sufficient period, he is put upon a low proteid, high carbohydrate diet, believing that we may in this way in some measure lessen the possibility of post-anesthetic acidosis. Other dietary changes are made for special conditions. Each patient undergoes a thorough examination prior to being given a general anesthetic. A chemical examination of the urine is made, and a microscopical examination of the sediment if there is reason for it. When any renal lesion or continued urinary obstruction is present or suspected, functional kidney tests are made. Blood pressure and cardiac abnormalities are brought to the attention of the anesthetist. If anemic, the hemoglobin is estimated. Unless contraindicated, morphine and atropine, in suitable dosage, are given subcutaneously one-half to three-

fourths hour prior to starting ether. We prefer the open-drop method of giving ether, yet concede that good etherizing may be done by other methods. While impressed by the reports of the experimental work of Yandell Henderson, we are unconvinced, by Henderson and Bryant's argument, of the greater safety of the closed and quasi-closed methods. Undoubtedly, acapnia, which they point out as the real danger, is at least a pertinent one, and the color sign a valuable warning and guide; yet, while our anesthetics amount to but few hundreds, we feel that the striking difference in the amount of post-anesthetic shock, nausea and other untoward results favor the open method.

An anesthesia slip is filled out, upon which is recorded the amount used, and all facts bearing upon the anesthesia. In bad ether risks, local novocaine anesthesia is used and just ether enough, when demanded, to meet the exigency. Every ether patient is watched to recovery by a trained nurse. This is insisted upon unless a physician is present. One physician in town does nearly all the anesthetizing. Occasionally one skilled in giving ether is called from a distance.

In brief, the safety and efficiency of operation is affected by the anesthetic, especially by the manner of administration, and we believe that the anesthetist should take his work seriously and expect and receive, in pay cases, a respectable fee.

Specimens for examination are sent to a pathologist. Such work only as urine, sputum and blood examinations, the inoculation of guinea-pigs, etc., is done in the hospital laboratory.

We have endeavored to develop something of a team, and while still very imperfect, we are pleased to say, with gradual improvement. Consultants are freely called, and when special conditions, as occasionally happens, indicate it, patients are referred to other and larger clinics.

Any patient, medical or surgical, admitted to the hospital, is considered primarily a patient of the physician in attendance prior to admission, and but temporarily under the care of whoever treats him. The benefit of his doctor's history of the case, and his advice, is sought and appreciated. On discharge we endeavor to relinquish the patient in a manner that he may carry the same high opinion of his family medical adviser which he held on his admission. We endeavor, with the assistance of the family physician and the visiting nurse, to follow up discharged patients, where any practical result may be obtained.

The Holden Cottage Hospital has not decreased our work, our assets, or our efforts. It has enabled us to study some of our cases and advantageously, we believe, to the good of all concerned. Its work has thus far been accomplished with very limited capital and it is continued existing as a factor in our efforts.

But one more factor in our structure will be mentioned. Obviously the present system of health departments, generally in vogue in towns, is no longer sufficiently effective. The duties of a board of health are invested in the board of selectmen, who delegate the executive work to someone designated by them as health officer, usually a practising physician. The scope of departments of sanitation has greatly broadened, in recent times, so that a separate board of health, at least, should be adopted. The best method of which we are aware involves, besides this, the union of a group of contiguous small towns in the employment of a trained health officer, in the manner now practised in the employment of school superintendents. The building laws for towns will undoubtedly be adopted generally as soon as the public become informed of their moral, sanitary and other benefits, and their effectiveness will be in ratio to the potency of local health departments. The initial movement toward changes of this kind must emanate from physicians.

Holden is at present, in this respect, still in the antiquated list, but we are hoping for the ultimate adoption of some such system as that above outlined.

## CIRCULATORY DISTURBANCE IN THE OBESE.

BY CLIFTON L. BUCK, M.D., DANVERS, MASS.

BEFORE entering upon the treatment of any cardiac affection it is necessary that a clear understanding of the various influences which may affect the circulatory organs in that particular case should be thoroughly understood. This is still more true if we desire to treat the patient on a rational system and not as a matter of rule of thumb, since, on careful analysis, the symptoms and circumstances which have led to the circulatory disturbance will be found to vary so widely that each case must be treated according to its especial indications.

It is the purpose of this paper to call attention to one factor in the treatment and prophylaxis of circulatory disturbances which, judging from the brief references in the text-books, and most special articles, has not received as much attention as it would seem to warrant, since it is a condition seen very frequently in general practice. I refer to circulatory disturbance in the obese; that is, circulatory disease in patients who are overweight for their height, age, and general build.

Obesity in youth and early adult life, unless complicated by cardiac disease, is, as a rule, not serious. After 35-40 years, however, men and women are very apt to take on weight more rapidly because of lessened muscular activity without a corresponding decrease in the amount and caloric value of food taken. It is at this time

that the degenerative diseases of the circulatory system often begin.

In many cases there seems to be a family tendency toward the development of obesity. This may or may not be the result of some perverted action of the so-called ductless glandular system. That this system does have some influence over metabolic processes may be inferred from the well-known changes which result from disturbance of thyroid secretion, as in exophthalmic goitre, myxedema, and in the marked bodily changes following castration. However, in practically all cases of obesity a greater or less excess of the fat-producing elements in the food exists. That this daily excess may be small and still result in the development of obesity may be appreciated when it is considered that the addition of only 10 grams of butter to the daily diet would result in the addition of approximately 90 calories to the fuel value of the diet. This excess continued for one month would result in the addition of approximately 2700 excess calories; food sufficient to supply an average-sized man for one day, at light work.

That an excess of fat may cause circulatory disturbance, or seriously affect the action of a heart crippled by some acute disease, as rheumatism, scarlet fever, or repeated attacks of tonsillitis, is readily seen when it is considered that the main purpose of fat in the body is to serve as a source of reserve energy. When an excess of food is taken, that is, when the caloric value of the diet is greater than is needed to meet the body requirements, the excess not needed is deposited as fat.

The fat deposits are particularly well marked around the heart, in the omentum, abdominal wall, and in the arms and legs. The fat around the heart interferes with the action of that organ by restriction of space in the pericardial sac, by deposit between the individual muscle fibers, and by its extra weight. In the abdomen the fat interferes with the action of the diaphragm, the principal muscle of respiration, thus tending to cause improper oxygenation of the blood. Since to supply the extra fat with nourishment more blood-vessels and a larger volume of blood are needed, in all these cases a high blood pressure is found unless there is cardiac dilatation. This means extra work for the heart to do and gives rise to cardiac hypertrophy with danger of dilatation and cardiac insufficiency. The excretory organs may become congested and in many cases albumen may be found in the urine, which suggests nephritis. Apparently, also, waste products of metabolism may be retained in the blood and give rise to various nervous symptoms, rheumatic and neuralgic pains.

All grades of cardiac insufficiency may be seen in this class of patients, but the most satisfactory and suitable cases for reduction treatment are those in which slight disorders of the

circulatory system are present and in which there is a moderate degree of obesity; cases in which the first signs of circulatory disease are beginning to appear. In some cases an increasing shortness of breath after slight exercise has been noticed; in other cases the only complaint may be pain in the region of the liver, gastric disturbance, or frequent nocturia, which Strauss has shown to be one of the earliest signs of beginning cardiac weakness. These cases are easily recognized, and a little physical exercise will show that the reserve force of the heart is becoming exhausted. Patients of this class are very common among our prosperous business and professional men and in women of middle age in all classes of society.

The indications for prophylaxis and treatment in this class of cases are clear and distinct. The disproportion between the fuel value of the food taken and energy output of the body must be righted, so that gradual reduction in weight will result and the work of the heart be lessened. For many years the dangers of excessive fat in acute illness have been recognized, even by the laity (as in the prognosis of acute infectious diseases, pneumonia, etc.), and Oertel has shown long ago the advantages resulting from the therapeutic measures directed toward a gradual reduction of excessive weight.

There are many who consider any attempt at reduction as weakening. This may be true of many of the "fast cures" which are extensively advertised in the popular magazines, and depend, as a rule, on purging and large doses of thyroid for their success. That it is not true of the slower method by proper diet is attested by the statements of patients who repeatedly say they feel stronger each week. In fact, if such is not the case, it is a sure indication that there is something wrong, and some feature of the case needs more investigation. The body depends largely on the proteid content of the food for its repair and growth. In the slow reduction by diet, proteid is usually allowed in amounts of 100 grams, or more, unless there are complications present, such as nephritis, when a moderate reduction may be made, if indicated.

In all these cases, without dilatation, as stated before, a high blood-pressure is found, and the question arises, what will be the effect of the reduction treatment on this? I can answer that the steady fall of blood-pressure is one of the most marked features as the patient improves. Conversely, where there is a low pressure resulting from the cardiac dilatation, the systolic pressure will rise gradually.

The greater the excess of weight, the greater the demand on the heart becomes and the smaller the surplus of reserve force to meet any unusual demand on the circulation. This is true, not only in cases of organic heart disease, but also in all conditions which impose

increased work on the heart, such as arteriosclerosis, atrophic nephritis, emphysema, etc. As a rule, it is impossible to exercise any direct effect on these lesions, but in obese cases we can combat the obesity and thus save the heart considerable extra work. This enables it to devote all its energy to overcome the disastrous effects of the pathological condition present.

There are several "cures" or systems of diet in obesity which are generally known by the names of their authors. Among the more important and widely known are, The Harvey-Banting Cure, the Epstein Diet, Oertel Cure, Schweinger System, and v. Noorden's System. While differing in several particulars, principally in the various proportions of fat, carbohydrate and proteid, and in the amount of fluid allowed, still in all the principle is the same,—to reduce the total caloric value of the food taken so that the excess body fat may be used in supplying this deficiency, while protecting the general nutrition of the body. In using any set system there is always danger of trying to adapt the individual patient to the diet rather than adapting the diet to the individual's needs.

At first glance it would seem as if the technic of arranging a proper diet would be most difficult, because of the formidable array of figures representing the various percentages of food elements and caloric values. Of course a knowledge of the composition and caloric value of the more common articles of diet is necessary, but in practice it is not necessary to weigh each article and compute its caloric value and the approximate amount of fat, carbohydrate, and proteid contained in grams.

It is easy to work out some simple system so that the total caloric value of the diet is reduced, and so long as care is used in treating the individual patient so that the general nutrition does not suffer, the desired result may be attained. The patient should report at the office each week to be weighed, and the effect of the diet on the weight and general nutrition noted.

In mild cases which apply at the office for treatment a careful inquiry should be made as to the kinds and quantity of food which constitute the average daily ration of the patient. In practice I have found it advisable to have the patient keep a list of the kinds and amounts of food taken for a week and bring it to the office. Then a proper diet should be made out for that patient. In many cases all that will be needed is a slight modification in the diet, such as a limitation in the quantity of bread and butter, pastry, etc. In other cases a more strict diet will be needed. It is not the purpose to make the diet so strict that it will be tiresome to the patient.

Considerable variety should be given to the action of the bowels, as proved by the increased use of vegetables, containing from 2 to 15% of carbohydrate. Many vegetables contain

than 5% COH and can be ignored in the caloric reckoning, as the little starch content goes through the bowels with the vegetable fiber, thus escaping absorption. If these are boiled in two waters the percentage of carbohydrate is considerably lowered. The restriction in the amount of bread and butter is usually most complained of by these patients, who are, I have found as a rule, excessive bread eaters. It is my custom to allow a moderate amount of potato and to insist on at least two other vegetables, to overcome somewhat the hardship resulting from the restriction in the amount of bread. It is generally believed that potato is fattening, but that it is markedly less so than bread is readily seen when we consider its analysis. Average bread consists of P. 9, F. 1.5, COH 53.3, while potato contains P. 2, F. 0.1, COH 18. By this method the coöperation of the patient is secured, and by the time the weight has been reduced to normal limits the habits of eating have been so changed that there is little danger of former habits being resumed and the weight regained, as so frequently happens when treated under the artificial surroundings of a sanatorium where a comparatively few weeks are spent.

In severe cases with œdema absolute rest in bed should be insisted upon for one to three weeks or longer. The heart rate is slowed when the patient is lying down, and as the heart receives its blood supply during diastole, better nourishment of the heart muscle results. The blood-pressure is also lowered. If the patient is restless and the heart action rapid and tumultuous, tincture of opium should be given in 5-10 drop doses as required, as it slows the heart's action and secures rest for the patient. Sufficiently large doses of digitalis may be given to secure its physiological effects if indicated, the amount of urine excreted in 24 hours being carefully noted, since as long as this amount is increased, or at least not decreased, no accumulative action need be feared. The diet at first should consist of skim-milk, cooked fruits, and eggs. When the condition has improved the diet may be increased by adding solid food at short intervals, bearing in mind that the food must be carefully selected as to quantity and quality, so that no overloading of the digestive organs may result. As a rule, it is best to limit the fluids to the skim-milk, which in itself is a mild diuretic. It should be given in small amounts frequently. When immediate danger is past, a rigid reduction diet should be prescribed so that a rapid reduction may be obtained, for if this favorable opportunity is allowed to pass, renewed cardiac attacks may be expected soon. In the beginning a loss of 3.5 pounds a week may be obtained, but as soon as the good effects of this become evident the diet should be rearranged so that only 3.5 pounds a month are lost. After a few months' treatment more freedom in diet should be allowed.

the aim being to retain the present weight for a few months. Then the diet should be again restricted so that a gradual loss of weight results. This method should be persisted in until the weight normal for that individual is reached. This may be a few pounds over or under weight as given in the various insurance tables.

The beneficent results of this method of treatment have been especially noted by the author in preventing the first signs of cardiac weakness in the slightly obese; in all cases suffering from diseases entailing an increased burden upon the circulatory system; and in the cases of extreme obesity. This is a particularly good field for prophylaxis, and it should be considered one of the most important duties of the family physician to prevent the development of obesity in all cases in which he recognizes cardiac weakness, as, for instance, valvular trouble developing from some of the acute infections of childhood, and in families which show an hereditary tendency toward obesity.

The following case reports from my cases are given to show the type of cases and results obtained by this method of treatment in suitable cases.

CASE 30. Female, married, age 39, house-wife. Feb. 5, 1914.

F. H. Negative.

P. H. Muscular rheumatism five years ago, which has persisted off and on ever since. Has had during the last twelve years four attacks of "nervous prostration." Legs have swollen for a long time when she is on her feet. Said to be due to "internal varicose veins."

P. I. For the last year has been very short of breath and at times gets weak and trembles. Has to sit down. Says she feels tired all the time. Has been treated for a long time for sour stomach and gas with no relief. Complaints of pain in right side under lower ribs. Nocturia three to four times. Bowels constipated. Menstrual periods regular. Flow small and pale.

Average Diet. Breakfast—cereal, bread and butter, cup of hot water. Dinner—potato, meat, bread and butter, pudding or pie. Supper—bread and butter, cake or cookies. Considerable candy between meals.

P. E. Height, 5 ft., 3 in.; weight, 183 pounds. Pulse, 80. B.P., 120. Obese. Eyes, nose, and throat, negative. Lungs, negative. Heart enlarged, apex 1 cm. outside left nipple line; at apex and base a soft systolic murmur is heard; not transmitted to left. Liver edge just below costal margin; tender. Both legs show marked edema to just below knees. Urine, pale, sp. gr., 1020; alb., 0; sugar, 0; sed. neg.

Diagnosis. Obesity; myocardial weakness with dilatation. Congestion of liver and other internal organs.

Treatment. Rest in bed; diet (skim-milk, eggs, and cooked fruits), until edema disappears. Then patient allowed up and strict reduction diet prescribed.

Outcome. July 21, 1915. Weight, 137½ pounds. Feels fine and has no shortness of breath, pain in side, or stomach symptoms. No nocturia. Walked to-day from her house to office, a distance of 1½ miles.

CASE 50. Female, married, age 60, house-wife; seen Jan. 18, 1914.

*F. H.* Father died of heart trouble, mother dead, age 65, cause not known; one brother living and well, one sister living but has heart trouble, one brother died of asthma and dropsy.

*P. H.* Has always been well until within the past four or five years, when she began to have a cough and frequent attacks of bronchitis; scarlet fever, mumps and pertussis as a child.

*P. I.* Comes in because of cough which has persisted most of the time for four or five years and is much worse at present. Raises considerable white sputum but never any blood. Cough is worse at night and whenever she gets tired. Has been moving the past week and has done considerable extra work. At present has some distress in stomach, and at times considerable gas. Distress not made worse by eating and is relieved by rest. Has noticed that she is growing more short of breath recently. Appetite good. Bowels are regular.

*P. E.* Weight, 182½ pounds; height, 5 ft. 5½ in. Pulse, 80. B. P. (s), 140.

Head, neck and throat negative.

Chest—Lungs show many "wheezes" and a few râles, mostly at the bases, posteriorly.

Heart—Area not determined because of excessive fat. First sound, faint and short. Soft systolic murmur at the apex. Action regular but somewhat rapid.

Abdomen—Full, soft, no masses or tender areas.

Liver edge felt about three fingers below costal margin.

Spleen not felt. No fluid.

Ext.—Moderate edema of lower legs.

Urine—Sp. gr., 1020. Alb. s. p. t. Sugar, 0. Sed. negative.

*Diagnosis.* Obesity; myocardial weakness with dilatation; chronic endocarditis (?); congestion of the liver.

*Treatment.* Rest in bed until edema is gone.

Diet (skim-milk, eggs, cooked fruit).

*Outcome.* Jan. 16, 1916. Weight, 155 pounds. B. P., 160.

Feels fine and has no cough or dyspnea. Has had no swelling of legs for several months. There is a moderate systolic murmur at the apex of heart, much more distinct than at first examination.

CASE 42. Male, age 52, salesman; seen Sept. 10, 1914.

*F. H.* Negative.

*P. H.* Has always been well except for pneumonia about 39 years ago; good recovery.

*P. I.* Comes in because of shortness of breath which has been growing worse for the last three to four years. Recently has had more cough, which is worse at night unless head is high. Any exertion makes breathing worse and is very apt to cause coughing. Thinks ankles have swollen a little lately. At times raises considerable sputum, and once or twice thinks he has seen little streaks of blood. Appetite good. Bowels are regular.

*P. E.* Weight, 177½ pounds; height, 5 ft. 6 in. B. P., 200. Pulse, 77.

Head, neck and throat negative.

Chest—Thorax moderately emphysematous. Lungs show a few squeaks scattered throughout both sides.

Heart—Area enlarged to the left and right. Regular and sounds distinct. At apex a systolic murmur is heard which is transmitted to the left.

Abdomen—Negative.

Urine—Sp. gr., 1022. Alb. s. p. t. Sugar, 0. Sed. negative.

Ext.—Slight pitting on pressure, over tibia.

*Diagnosis.* Obesity, emphysema, chronic endocarditis, nephritis (?).

*Treatment.* Reduction diet.

*Outcome.* March 20, 1916. Weight, 147 pounds. B. P., 164.

Feels fine and has no cough or shortness of breath, except on vigorous exertion. Cardiac area and sounds unchanged.

CASE 35. Female, married, age 49, house-wife; seen Oct. 18, 1915.

*F. H.* Father dead, accident; mother dead, child-birth; two brothers and one sister living and well.

*P. H.* Has had six children, all normal labors; has had frequent and severe attacks of tonsillitis all her life; scarlet fever, pertussis, measles in childhood.

*P. I.* Comes in for shortness of breath and swelling of legs which began about eight years ago and has steadily increased despite varied and vigorous treatment.

*P. E.* Weight, 183½ pounds; height, 5 ft. 3 in. Pulse, 80. B. P., 180.

Head and neck negative. Throat shows large and ragged tonsils, the crypts of which are filled with cheesy material. Pillars reddened.

Chest—Negative except for poor expansion.

Heart—Area enlarged; blowing systolic at the apex transmitted to the left. Regular and moderately rapid.

Abdomen—Liver edge felt about two fingers below costal margin.

Ext.—Marked edema of lower legs.

Urine—Sp. gr., 1028. Alb. s. t. Sugar, 0. Sed., rare hyaline cast.

*Diagnosis.* Obesity; chronic endocarditis; cryptic tonsils.

*Treatment.* Removal of tonsils advised but refused.

Reduction diet.

Rest in bed until edema gone.

*Outcome.* Feb. 10, 1916. Weight, 159½ pounds.

Feels fine and has no edema of legs; no shortness of breath; walked to-day from her home to office, a distance of about one mile, easily.

CASE 54. Female, married, age 58. One child. Nov. 27, 1914.

*F. H.* Father died of heart trouble, dropsy. Mother died of kidney trouble. One sister living, Bright's disease.

*P. H.* Always has been well except for attacks of severe colic which began about six months after birth of child, and has recurred at intervals ever since.

*P. I.* Comes in because of shortness of breath which has been increasing for the past few years. Has considerable regurgitation of serum. Latter fluid into mouth. Appetite is good. Body emaciated, has been gaining in weight considerably for the past few years.

*P. E.* Weight, 199½ pounds; height, 5 ft. 6 in. B. P. (s), 210. Pulse, 117.

Head, neck and throat negative.

Chest—Negative.

Heart—Area enlarged to the left and right. Regular and sounds distinct. At apex a systolic murmur is heard which is transmitted to the left.

Abdomen—Liver palpated about two fingers below costal margin. Slight distress in region of gall-bladder.

Ext.—Moderate edema.

Urine—Sp. gr., 1020. Alb. s.t. Sugar, 0; Sed., many hyaline and granular casts.

Diagnosis. Obesity, chronic endocarditis; chronic nephritis, gallstones (?).

Treatment—Rest in bed, reduction diet. Epsom salts as required to keep bowels active.

Outcome. March 24, 1916. Weight, 163 pounds. Breathing fine, still has considerable stomach distress at times. Heart area and murmur unchanged. Urine examination, many hyaline and granular casts. Edema of legs. B. P., 180.

## JEAN-PIERRE DAVID: THE MAN WHO POTTED POTT.

By JOHN RIDLON, M.D., CHICAGO.

IN the BOSTON MEDICAL AND SURGICAL JOURNAL of June 3, 1915, Dr. R. W. Lovett presented an appreciation of "Percival Pott: His Times and His Work."

Pott lived when "quackery was rampant." If we may judge him by his paper on "Palsey of the Lower Limbs, Which is Frequently Found to Accompany Curvature of the Spine," he did not escape the taint of his times. Then, as now, a quack may become preëminent; then, as now, a learned and skillful practitioner of medicine or surgery may become preëminent; but the learned and skillful practitioner of medicine or surgery who happens to be born with the instincts of a quack has all others out of the running.

In his time Pott was counted a skillful surgeon—"Surgeon to St. Bartholomew's Hospital during forty years." His writings on hernia, head injuries, hydrocele, fistula in ano, and fractures and dislocations, have been forgotten for more than a century; the three things that have come down to us, after 138 years, are: that he broke his ankle going to Southwark; bought a door and had himself carried home on it; and wrote the paper above mentioned on palsy of the lower limbs, which gave his name to caries of the spine, of the treatment of which he appears to have been profoundly ignorant.

The knowledge which Hippocrates had 400 B. C., the knowledge which Galen had in the second century and the knowledge which Paré had in the sixteenth century, A.D., and the work which was then being done in Paris all passed him by.

It is generally supposed, and often stated, that Pott first described Pott's disease. Nothing could be further from the truth. He did not even describe the disease in his paper on palsy. He does not appear to have recognized any difference in the causative effect of kyphosis, scolio-

sis and lordosis on the production of the palsy, or to know that there is such a thing as caries of the vertebrae, or that it had really anything to do with the palsy he writes about. All he appears to have aimed at was to get his new method of treatment into print before any other practitioner heard of it and forestalled him.

And what was this wonderful treatment? It was to cut a gash or burn a hole in the meat on each side of the spine, place therein a kidney bean, and every third day, sprinkle into the wound some finely powdered Spanish flies to ensure keeping the sore open and discharging abundantly! He ignored the fact that this treatment kept the patient in bed, and kept him lying on his face in the most favorable position for the cure of the caries of the vertebral bodies. He does not even give a good clinical description of the palsy (see Lovett's quotations). He was sure that the arms were never affected, and he recognized sensory disturbances, particularly in the thighs, before any motor disturbances appeared. He did not know that the reflexes were changed.

He recognized an early enlargement of the vertebral bodies and some change in their structure, but he does not appear to have recognized this as a diseased condition—only as a condition preceding caries. But when caries had developed, Pott looked upon the case as hopeless. He says: "That if from inattention, from length of time, or any other circumstances, it happens that the bodies of the vertebrae have become completely carious, and the intervening cartilages are destroyed, no assistance is to be expected from the proposed remedy." He unhesitatingly asserts that the placing of setons and issues at each side of the kyphotic spine will cause the kyphos to straighten, or at least become straighter, and the patient taller. To quote: "I have waited a sufficient length of time, and treated a sufficient number of subjects to be clear in the truth of what I have asserted as far as such time, and such individuals go. That the patients whom I have attended in the early part of the distemper, of whatever age, have all got well; that is, have all not only regained the use of their legs, but have become healthy and fit for any exercise or labor, as numbers can testify who have seen them daily. Most of them have become much straighter, some quite straight, and all of them perfectly free from all kinds of inconvenience arising from the curve." Again: "That as far as my experience goes, I have not the least doubt that if the means proposed be made use of before the bones are become really carious and rotten, they will always be successful. When, indeed, a truly rotten state of the bones takes place, no good is to be expected from this or from anything else; but it should be observed, at the same time, that this never happens but when the distemper is of very old date and when this is the case, the whole machine is disordered and the patient

is so truly and so generally distempered that there can be no reasonable expectation from anything."

The cry of Pott is the cry of the quack of all times: "I can cure all curable diseases by my wonderful treatment. Cases that cannot be cured by my treatment cannot be cured by any treatment whatsoever."

Now attend to what Jean-Pierre David, whose prize essay was published in Paris the year before Pott wrote, has to say regarding caries of the spine.

Discussing the rationale of the treatment of fractures by rest, he says: "But there are many other cases in which nature appears to have the same views as in fractures and in which the indications for rest are as precise as in these accidents."

His first case of "Pott's disease" (!) he saw in 1766, and describes as follows: "Having been violently beaten, at the age of 13, by his father, he felt, a few months after, a weakness in the spine, attended with pain and difficulty in keeping the upright posture. He walked with great difficulty, and afterwards could not walk without leaning upon a stick, with his body bent forward. These first symptoms, which continued for more than six months, were followed by a fever accompanied with difficulty of breathing, and pain in the middle of the back, without any apparent swelling externally.

"These symptoms were relieved by bleeding and other remedies and the patient seemed restored to his former state, but the difficulty of walking and supporting himself increased by degrees, and at length a tumor was formed toward the lateral and posterior part of the last false ribs, the increase of which was very slow, and made no change in the colour of the skin.

"This tumor, extending itself, gained the region of the loins, and more than six months after its appearance, the skin became inflamed, grew thin and, by the assistance of maturing poultices applied to the tumor, a fistulous opening was made in it from which there issued, according to the patient's account, more than a quart of matter as white as milk. The discharge having continued very plentiful for three months without hope of cure, the parents, tired with the length of the disease, took the resolution of sending the young lad to the Hospital. When he came there he had a fistulous opening on the right side of the lumbar region which furnished an ichorous and plentiful discharge; a slow suppurating fever accompanied, and every appearance seemed to show that death would soon terminate this disorder. A plectet of soft ointment only was put upon the fistulous orifice, and the disease was left to nature.

"I frequently saw this patient, who, being better fed and more attended than at home, began to recover a little from the deplorable state to which he had been reduced. He particularly kept very quiet in his bed, and his spine

was then incurvated with an evident projection outwards, towards the last dorsal vertebra. About two months after he came to the Hospital, the matter which oozed from the fistulous opening grew thicker and less plentiful, the countenance appeared better, the pulse less frequent, and he began to give some hope of recovery. This hope was confirmed six weeks afterward, for the discharge still lessened, and the patient began to feel some degree of strength in his spine. Two months after this last period, the fistulous orifice was closed, and the patient began to walk with a stick; but he was crooked, and seemed to have lost much of his former height.

"From the accidents this patient had undergone, and the deformity the spine had contracted during the course of the disease, I imagined that some of the dorsal vertebrae had been affected with caries; that the remains of them, after having been confounded together and after having been in a state of granulation, had at length acquired a degree of solidity sufficient, in some sort, to supply the bodies of these bones. I could not but consider rest as having been the chief promoter of this salutary end; and the subsequent facts appear to have completely confirmed my conjectures on this point.

"First, the patient who had been the subject of the preceding observation, and whom I had always kept within my notice, having been seized, in 1769, with a peripneumony of which he died, I was allowed to inspect the body, and my first care was to take notice of the disorders the spine had experienced three years before. I found, as I expected, several vertebrae, the bodies of which were confounded with each other; these were the ninth, tenth and eleventh of the dorsal vertebrae, which had lost at least half of their longitudinal dimensions, while their spinal processes, which had not suffered the least alteration, formed a projection and a remarkable convexity outwards."

David then goes on clearly to differentiate these cases of kyphosis from cases of lateral curvature, and to point out how those cases of kyphosis accompanied by abscesses never recover until "after a long continued rest," to enable the affected parts to gain "a sufficient degree of solidity." We should wait "till, by rest and a horizontal position, the pieces that compose the column shall have lost that morbid state of softness which has disposed them to be thrown out."

He then describes cases of spondylitis in the lumbar region with abscesses passing down underneath Poupart's ligament or into the iliac foramen.

As to the frequently accompanying abscesses he says, "The surgeon who makes this opening and who sees that he is giving rise to a great quantity of matter, confined for a long time to swellings of this kind, congratulates himself upon an event which he looks upon as

but turn out for the good of his patient; but the patient, who for some months past had experienced no evident degree of fever, who suffered but little, who had perhaps preserved his appetite, who slept, and who had complained of no other symptom but that he could not keep his back upright, is far from being relieved by this operation, at least if he be, the relief is not of long continuance; for the matter forming the tumor, which at the time of the opening was as white as milk and without smell, soon contracts a considerable stench, a fever comes on, the pulse becomes quick and small, and the patients pretty frequently die towards the thirteenth day."

David knew that these abscesses, when left alone, and the patient put at rest, would not infrequently disappear; and he reports such a case, a young woman with caries in the lumbar region, who had a psoas abscess with a tumor the size of one's fist below Poupart's ligament. Under treatment by rest the abscess disappeared without opening. He knew that so long as "the matter is still sheltered from the external air, and undergoing no change, produces no mischief in the parts surrounding it." He knew that the slow evacuation (by spontaneous opening) or absorption of the matter, "as slowly as its collection was formed, the parts which compose the cavity must return to their proper state as gradually as they were disturbed from it, without accident and without inconvenience."

"With respect to the bones that are primarily affected, and which have almost adopted the nature of flesh during the long and important process of exfoliation, no sooner are they disengaged from the loose pieces than they begin to recover their solidity; and if several vertebrae . . . . . have partaken of the injury, they form among themselves a common mass of ossification that in some measure supplies their bodies, and terminates this important cure, which, as we may observe, can only be the work of nature, time and rest."

And now after the lapse of 138 years, who has given, who can give, a more illuminating picture of spinal caries? As to the treatment of the disease, and its complications, we may differ from David and from each other in minor details, but the broad general principles of the treatment have in no way been added to or altered.

Placed side by side with Jean-Pierre David, the real man, Percival Pott, with his setons and issues, his kidney-beans and finely powdered cantharides, bulks very small and a very pathetic figure.

LONDON DEATH RATES IN JULY.—Statistics recently published show that the total death rate of London for July, 1916, was only 10.7 per 1,000 inhabitants living. Among the several districts and boroughs the highest rate was 14.8 in Holborn, and the lowest was 7.7 in Wandsworth.

## Clinical Department.

### REPORT ON THE CLINICAL SYMPTOMATOLOGY AND LABORATORY FINDINGS IN THREE CASES OF GENERAL PARESIS UNDER INTRAVENOUS ARSENO-BENZOL TREATMENT.\*

By G. E. MOTT, M.D., AND S. M. BUNKER, M.D.,  
WORCESTER, MASS.,

Assistant Physicians, Worcester State Hospital,  
Worcester, Mass.

Mr. President and Fellow Members of the Worcester District Medical Association:

THE recent increase of literature on the subject of syphilis and its action upon the nervous system, together with the results obtained from the intensive treatment of salvarsan now being practised in our state hospitals for the insane and at a number of the larger general hospitals, suggest that a brief presentation of the history, symptomology and laboratory findings in three cases here under treatment for the past three months will be of interest at this meeting of the Worcester District Medical Society.

Most of the cases of central neural syphilis in this state are classified as general paresis. The percentage of admissions of this disease to our state hospitals for Massachusetts has been given at 9%.

Hitherto the diagnosis of general paresis has been made upon the appearance of such classical symptoms as the Argyll-Robertson pupil, altered knee-jerks, ataxia, loss of judgment, emotional instability, etc. The diagnosis was confirmed by the well known Wassermann reactions in the blood and spinal fluid.

We have come to look for the following six laboratory tests in confirmation of the diagnosis of general paresis:

1. Positive colloidal gold reaction of Lange (gold chloride test).
2. Globulin—present and increased, Noguchi—butyric acid method.
3. Albumen—present and increased.
4. Number of lymphocytes per c. m. increased from 10 to 400.
5. Wassermann reaction in blood serum.
6. Wassermann reaction in spinal fluid.

It is interesting to note that practically nothing is known of the reactions of the spinal fluid prior to the onset of the clinical symptoms of general paresis. Recent work by Southard and other observers, however, tends to show that the six positive laboratory findings for general paresis are present months, and perhaps years, before the appearance of the classical clinical symptoms. With these findings in view, spinal punctures, as well as the regular blood serum tests, are fast becoming routine procedure.

\* Read before the Worcester District Medical Society on March 8, 1916.

Moore, in his translation of Kraepelin's discussion of general paresis in the last edition of his text-book, states, "The actual beginning of paresis consists, as a rule, of rather indefinite symptoms which are usually interpreted as nervousness. They are apt to be excitability, a hasty, irritable, whining manner, anxiety states, absent-mindedness, fatigability, mental dulness, forgetfulness, a tendency to sleep or persistent sleeplessness. Accompanying these are headaches, migraine with scotomata and vomiting, giddiness, cardiac palpitation, excessive sweating, rheumatoid pains, numb feelings, muscle twitchings, writer's cramp, brief weaknesses, abdominal cramps and intestinal obstruction. In the further course, the mental and physical symptoms may progress collectively or individually with very irregular rapidity. Thus there are cases in which even severe disturbance of speech and writing, with tabetic signs and lost reflexes, may exist for a long time before any marked involvement of memory or intellect can be discovered. On the other hand, the mental symptoms may be fairly prominent while physical examination reveals at first only indefinite and non-characteristic changes. This fact furnishes a wide opportunity for errors in either direction, before the cytological, and especially the serological tests afforded us a means of verifying our opinion even in the earliest stage of the disease."

With these points in mind, I will briefly give the chief facts in the histories of three cases of general paresis now under treatment with salvarsan.

This treatment was recommended by the Massachusetts State Board of Insanity. As salvarsan was not on the market, the Canadian preparation, diarsenol, was used until the cheaper price of the Philadelphia Dermatological Laboratory's product, arsenobenzol, made its use advisable.

The drug has been given bi-weekly, intravenously, in the arms. Following the earlier treatments a distinct reaction occurred,—chills, fever, headache, nausea, and vomiting. The most constant symptom was a nervous chill lasting from ten to twenty minutes and appearing from ten to thirty minutes after treatment.

Some local infiltration and organization has been caused by leaking of drug during administration, but these discomforts have readily yielded to application of ice and massage. Some variability in the acidity of the drug has been noted. Frequent urinalyses have shown only occasional traces of albumen in ease of T. H. The body weights have shown scarcely any variation during the past three months.

CASE 29742. G. H. D. Patient is a French Canadian, age 38, white, single social state, Roman Catholic religion. In the United States 50 years. The family history states that the father died of accident, mother of shock at age of 72, one

brother of pulmonary tuberculosis, six sisters living and well.

*Personal History.* Early life unimportant. In school 11 years. Employed as a mill hand. Was steady and efficient, well liked, always well and enjoyed a happy disposition. Used alcohol moderately. Never arrested for drinking. Onset of present trouble began about Sept. 17, 1915. Complained about his heart. Returned medicine prescribed by physician to doctor claiming that the latter had drugged him. Later claimed that his relatives were drugging his food and for this reason stopped eating. Was hallucinated, talking to himself, saying that he could hear little fairies. Saw them flying around and sitting beside him. Regularly committed to the Worcester State Hospital, Oct. 4, 1915. Physician's certificate described him as both excited and depressed at times; as suffering from delusions of persecution. Claimed that members of the Lowell police force had been after him for six weeks; that a medicine with nine hundred and a half grains of poison had been given to him; that he had seen his death certificate signed, and that \$500 as a bribe had been offered to somebody to secure his death. Further described as troubled with insomnia. On admission to hospital, interview found him approximately oriented, with well marked ideas of poisoning, acute auditory and visual hallucinations for the past two weeks. These hallucinations were highly suggestive of alcoholic influence, and this fact, together with the admission that he had been drinking regularly three glasses of beer before, and perhaps from four to seven glasses after, supper daily, led to the diagnosis of alcoholic hallucinosis in a case of general paresis. In addition to the foregoing hallucinations, patient complained that he had a feeling that little fairies were about him—"they feel like little pin pricks"—suggested impairment of tactile sensations. During the earlier part of his residence he was very suspicious in attitude and seemed apprehensive of some harm coming to him. By degrees his hallucinatory episode abated, his attitude became more sociable and he adjusted himself to his surroundings, although remaining somewhat slovenly in his dress and habits. Following treatment of salvarsan he seemed to improve until February 22, when he flatly refused further treatment. A change in his conduct occurred on February 19, when he began to act peculiarly—appeared depressed, was noticed kneeling about the ward in attitude of prayer, was mute to all questions and would not cooperate with even such simple procedures as the taking of his temperature.

*Physical and Neurological Examination.* The skin showed copper point discolorations, entire body covered with papillomata ranging in size from a pea to a horse chestnut. Glands slightly enlarged in groin, axillary and cervical chain. Mucous membranes pale. Pupils unequal, right larger than left, right does not react well to light. Slight exaggeration of the deep reflexes; coarse, rapid, irregular tremor of extended hands. Percussion over impaired over bases of lungs positive. Slight atherosclerosis. Blood pressure 120. Very moderate posterior surfaces of scapulae. Scapular area on glans. Urinalysis negative. No albumen in urine. Menstruation normal. No other abnormal reflexes.

*Treatment.* T. H. D. Patient is a French Canadian, age 38, white, single social state, Roman Catholic religion. In the United States 50 years. The family history states that the father died of accident, mother of shock at age of 72, one

a. *Diarsenol.*

From January 5, 1916, to January 21, 1916, 6 intravenous injections (alternating arms) of diarsenol, given bi-weekly in doses varying from 0.3 gram to 0.6 gram—total of 2.7 grams of diarsenol.

b. *Arsenobenzol.*

From February 2, 1916, to February 18, inclusive, four intravenous injections (alternating arms) of American preparation, arsenobenzol, in doses varying from 0.3 to 0.6 gram—Total of 2.1 grams arsenobenzol.

Patient has steadfastly refused treatment from February 22 to present date. (Repeated punctures on account of small calibre of veins found necessary causing patient to grow discouraged and irritable. When told of his negative laboratory findings with idea of encouragement, he decided that he was cured.)

*Laboratory Findings:*

a. *Wassermann Reactions in Blood Sera.*

From October 13, 1915, to January 25, 1916, inclusive, 6 positive reactions reported by the State Department of Health laboratory.

February 7, 1916, negative reaction.

February 18, 1916, negative reaction.

February 25, 1916, doubtful reaction.

b. *Wassermann Reactions in Spinal Fluid.*

Nov. 10, 1915, positive reaction.

Feb. 17, 1916, unsatisfactory reaction.

c. *Spinal Fluid Examinations.*

1. Gold Chloride Test.

Nov. 8, 1915: 1-1-2-1-±-±-±-0-0-0—  
positive?

Feb. 14, 1916: 3-2-2-±-0-0-0-0-0-0—  
positive.

2. Cytological Count.

Nov. 8, 1915, fresh fluid clear—cells per c. m. equals 125.

Feb. 14, 1916, fresh fluid clear—cells per c. m. equals 3.

3. Albumen Test.

Nov. 8, 1915, plus, plus, plus.

Feb. 14, 1916, plus.

4. Globulin Tests.

Nov. 8, 1915, Ross-Jones test plus. Noguchi test plus.

Feb. 14, 1916, Ross-Jones test plus. Noguchi test plus.

CASE 29578, A. B. A man aged 36, Italian, in the United States 10 years. A waiter by occupation. Successful in business. Committed to the hospital on June 18, 1915. The committing physicians gave the onset of present attack about June 1, 1915, describing the patient as suffering from expansive and grandiose ideas (patient said he had about two hundred billion dollars and that he was going to give it to everybody that wanted it; that he was going to build restaurants and feed the poor people). Patient was further described as suffering from insomnia, excitement and talking garrulously. The family history states that one paternal uncle died of tumor of the brain. Patient is said to have been nursed by a woman who later died of syphilitic infection. The personal history credits the patient with little education, describes him as thrifty and saving, drank liquor moderately. Married April, 1914. One child born January 25, 1915. The onset of his present trouble is said to have been sudden,

occurring June 1, 1915, when he had some slight trouble with his employer, gave up his job, developed extravagant ideas, was talkative and excited and was sent to the Psychopathic Hospital, June 8, 1915.

On admission to this hospital he was noisy, excited, crying, showed loss of emotional control, hoarse from excessive use of voice, had a temperature of 101.2, pulse 90, respiration 20. Admitted contraction of syphilis about 20 years ago at Glasgow, Scotland, where he received treatment every week for a year, of mercury and potassium iodide. The doctor told him that he was cured. Five years later troubled with a sore upon his head; ten years ago in Boston, a right-sided bubo appeared and was treated surgically. Something over a year ago he desired to get married, and had his blood examined. A positive Wassermann was reported. He therefore took mercurial injections four times a week to the number of 106. The injections were given intramuscularly in the back; all of this treatment is based upon statements of the patient. In his capacity as waiter he claims to have accumulated \$12,000. About the middle of May, 1915, patient stated that he experienced a feeling of strange elation, thought that he would like to buy a theatre and wanted to buy everything to help humanity. Thought that the Boston Psychopathic Hospital was a present to him. During fifteen days he thought that he was boss and undertook to run the place. In his dreams he talked with his father and mother. During the next two months patient was highly excited, engaged in destructive acts, such as tearing his clothing and bedding, digging into the plaster of the walls of his room, taking the springs from his bed to make keys, successfully picked one or two locks, stole spoons and other metal articles to furnish material for his keys. During this period he required frequent sedatives to relieve noisy insomnia. Following this there was an improvement for about a month, followed by a relapse of two months. About January 1, 1916, he was transferred to Gage Hall 2, where he was a great trial to the attendants until he came under the influence of the salvarsan treatment. At the present time he reacts quite naturally to his surroundings and shows a remarkable general, clinical improvement.

A physical and neurological examination at time of admission showed some bruises and discolorations following violent activities preceding admission. General feeling of exaltation. Argyll-Robertson pupils. Irregular, rapid tremor of extended fingers, gelatinous tremor of the tongue margin. Some slight pulmonary changes. Blood pressure 150. A slight discoloration at coronal border of the genitals. Urinalysis was negative.

*Treatment.* Total arsenic drug equals 9 grams.

a. *Diarsenol.*

From Jan. 5, 1916, to Jan. 18, inclusive, 5 intravenous injections. Total, 2.1 grams.

b. *Arsenobenzol.*

From Jan. 21, 1916, to March 7, 1916, inclusive, 12 intravenous injections. Total, 6.9 grams.

*Laboratory Findings.*

a. *Wassermann Reactions in Blood Sera.*

From July 9, 1915, to Feb. 18, inclusive, 12 positive reactions reported by the State Department of Health Laboratory.

Feb. 25. Unsatisfactory reaction.

March 4. Positive reaction.

March 4. Positive reaction.

 Noguchi, plus, plus.

CASE 29461. T. H. A man aged 48, native American of Irish parentage. Plumber and professional baseball player by occupation. Civil condition, married. He was committed to this hospital on March 18, 1915. The physicians' certificate describing patient as cleanly, talking incessantly and boisterously, ideas of exaltation, expressing queer moral and religious ideas, marked insomnia, with "hallucinations of business deals." The family history is negative to insanity. The personal history furnishes a record of excessive use of alcohol from age of 19 to 43. Successful in his business. Married six years ago. No children. Had reputation for drinking and carousing while in baseball company. Generous and jolly in disposition. Venereal history unknown. The onset occurred about March, 1914. Began with nervousness and insomnia—six months ago considered taking a rest for nervous breakdown. Talked about big business deals. Eight days ago became excited, talkative and his conversation showed repetition. A physical and neurological examination showed a geographic tongue; right naso-labial fold more marked than the left. General feeling of well being. Pupils are equal and regular, but react sluggishly through a small arc to light. The right hand grasp is a little stronger than the left. Walks on a wide base. Reflexes exaggerated throughout. Knee-jerks third degree. Slight radial sclerosis. Blood pressure 148. Pyorrhea alveolaris. No genital scars. Urinalysis negative.

In the early part of his hospital residence, he was noisy, loud talking, distractible, generally excited and garrulous, showed pressure of activity, restlessness in his room, lack of judgment, rambling and boastful in conversation, full of explanations which failed to explain. Later he quieted down but remained emotionally unstable, with impaired judgment, tendency to fabrication, talkative, voluble, expansive and grandiose in his ideas. Admits venereal infection about six years ago.

On May 18, he was recorded as reacting to auditory hallucinations, talking to imaginary friends outside of his window. Disoriented for time, excited, elated, at times aggressive and violent, requiring the use of sedatives. By November, 1915, he had quieted down and had gained sufficient self-control to live in Lincoln 1.

*Treatment.* Total arsenic drug equals 8.7 grams.

From Jan. 5, 1916, to Jan. 21, inclusive, 6 intravenous injections. Total, 2.7 grams.

b. *Arsenobenzol*.

From Jan. 25, 1916, to March 7, 1916, inclusive, 11 intravenous injections, total 6 grams.

### Laboratory Findings.

a. *Wassermann Reactions in Blood Sera.*

From Jan. 6, 1916, to Feb. 5, inclusive, 8 positive reactions reported by State Department of Health Laboratory.

Feb. 7. Negative reaction.

Feb. 18. Positive reaction.

Feb. 25. Unsatisfactory re

March 3. Positive reaction.

March 4. Positive reaction.

#### b. Wassermann Reactions in Spinal Fluid

March 24, 1915. Positive reaction.

March 3, 1916. Positive reaction.

c. *Spinal Fluid Examinations.*

1. Gold Chloride Test.

Jan. 24, 1916. 4-4-3-4-4-3-2-1-=-= positive.  
Feb. 28, =-±-1-1-±-0-0-0-0-0-0-weak positive.

## 2. Cytological Count.

Jan. 24. Spinal fluid too bloody.

Feb. 28. Cells per c. m. in fresh fluid, 6.

### 3. Albumen Test.

Jan. 24. Plus, plus, plus.

Feb. 28. Plus, plus.

#### 4. Globulin Test.

Jan. 24. Ross-Jones, positive. Noguchi test, positive.

Feb. 28 Ross-Jones, plus. Noguchi test, plus.

Briefly summarizing the foregoing three cases:

1. The onset of the disease, as determined by statements of physicians, relatives and of the patient himself, occurred as follows:

In one case, ten days prior to commitment,

In another case, fifteen days prior to commitment.

In still another, one year,

In the light of subsequent treatment, early diagnosis of general paresis, or at least of syphilitic involvement of the central nervous system, is of the utmost importance. Other observers, as I have already tried to point out, have shown that a much earlier diagnosis can be reached through persistent and thorough laboratory examinations than from the appearance of consistent clinical symptomatology.

Following treatment:

2. Definite clinical improvement has occurred in two of the patients. One patient has shown resistiveness and lack of cooperation to such an extent as to classify him as not improved.

### 3. Definite results in the laboratory findings

a. Gold chloride test, although still positive, much reduced in two cases. Slightly increased in the case referred to treatment.

b. Allman tests reduced to 10 + 10 cases from three phases to one phase.

Calculation tests as well as the trend in

- one case; unchanged in other two cases.
- d. Cytological count reduced in one case from 125 to 3 cells per c. m. Low normal count in both of the other cases (3 cells in one, 6 cells in the other).
  - e. Wassermann reaction in spinal fluid: In one case from positive to unsatisfactory—Nov. 10 to Feb. 17 (case of G. H. D.). In other two cases unchanged, remaining positive.
  - f. Wassermann reaction in blood sera: Showed three negatives and one doubtful reaction in one case (G. H. D.). One unsatisfactory reaction in case of A. B. One negative, one unsatisfactory, and all other reactions positive in case of T. H.

### Medical Progress.

#### ELEVENTH REPORT OF PROGRESS IN ORTHOPAEDIC SURGERY.

BY ROBERT B. OSGOOD, M.D., ROBERT SOUTTER, M.D.,  
HERMANN BUCHOLZ, M.D., HARRY C. LOW, M.D.,  
MURRAY S. DANFORTH, M.D., BOSTON.

(Concluded from page 314.)

#### RICKETS (Continued).

LOVETT<sup>26</sup> has made a careful study of between 600 and 700 roentgenograms of rickets taken from between 7000 and 8000 roentgenograms at the Children's Hospital, Boston. Thus rickets constituted about 9% of their total plates. We give a fairly complete review of this article, which seems to us of much value. In this study he found the cases divided themselves into three groups or stages, with fairly well marked characteristics. Of the first stage there were two types: 1. The mild type, in which the ends of the diaphysis become frayed out, instead of clear cut, and the epiphysis casts little or no shadow, while the centre of ossification is small or absent, and at times appears multiple. The whole joint is surrounded by a hazy cloud, and the diaphysis on the whole contains less lime than normal. Up to this point deformities have not begun. 2. In the severer type the epiphyseal appearances are similar, but more marked. In the diaphysis severe general bone atrophy exists, and there is pronounced periosteal thickening associated as a rule with fracture of the bones, most often in the arms. These cases of multiple fracture are very common. In the second stage the shadow of the epiphysis becomes more marked. The area is ragged and irregular about the margin and calcification is more marked at

some points than others, which results in a characteristic mottled appearance. The ends of the diaphysis begin to broaden, especially on the side on which the strain is greatest, which produces a ledge or lip next to the epiphyseal line. In bow-legs this is found on the inner side of the tibia and femur, and in knock-knee on the outer side of the same bones. The diaphysis in the second stage begins to give a more definite shadow. The region next to the epiphysis is striated longitudinally and is the area of maximum disturbance. At the epiphyseal end of the shaft there is generally a transverse area of increased density reaching about a quarter or a half inch from the epiphyseal line, bounded at the end farthest from the joint by a fairly sharp line. This continues into the third stage, in which it may become more defined, and resembles in many respects similar changes in syphilitic bones in infants, described as osteochondritis. At the end of the diaphysis next to the epiphyseal line, there often appears in the late second or early third stage a clear transverse white line, showing an increased deposit of lime in the lower end of the shaft. This is apparently not to be distinguished from the "white line" which is described as characteristic of scurvy, but which is equally characteristic of rickets. A longitudinal change occurs along the shaft of long bones, consisting of cortical thickening on the concave side of the bones. This is one of the most important characteristics in differential diagnosis. Further changes in this stage consist in "chambering" of the interior of the bone, where light areas in the shaft indicate the absence of marked bone deposit and heavier lines of ossification show the irregular development of trabeculae. In the third stage the epiphysis is more normal in contour and density, the lipping of the diaphysis persists, and there is a consequent discrepancy between the diameter of the diaphysis near the epiphyseal line and the epiphysis. This relative difference in size is characteristic of the disease. The shaft becomes more dense, and its compensatory thickening on the concave side of the curvature persists. Under differential diagnosis, the author states that in scurvy, while there may be marked changes in the diaphysis, the epiphysis shows a clear outline. This, too, is true in chondrodystrophia fetalis, also in hereditary osteogenesis imperfecta. The roentgenographic diagnosis of rickets and congenital syphilis is the most uncertain. Here again the difference in the appearance of the epiphysis in the two conditions is most important. In syphilis the epiphysis is not clouded and its outline is clear, while there is in syphilis marked cloudiness about the joint, which is not the case in rickets. Extensive periosteal changes are common to the two diseases. In the severe type of acute rickets, severe periosteal thickening, very frequently associated with fracture, is found. Such periosteal disturbances diminish

with the progress of the disease and show no tendency to bone formation, such as is the case in the periostitis ossificans of syphilis. Moreover, fractures are rare in syphilitic infants. The irregularities in the medullary shadow of the shaft in syphilis are due to irregular increase in density. The irregularities in rickets are related primarily to diminished density. In the later stages of both diseases the occurrence of cortical thickening is highly differential. In rickets the thickening is endosteal in origin, and is always on the concave side of the curve, while in syphilis the thickening is periosteal or osteoperiosteal and is very uniformly on the convex side of the curve. Lovett considers that osteotomies should not be done during the active stage, but only when the epiphysis presents a rounded clear outline.

#### CONGENITAL DEFORMITIES.

##### *Anteversion of the Neck of the Femur in Connection with Congenital Dislocation of the Hip.*

Hibbs<sup>27</sup> calls attention to this deformity of the femur as a cause of failure to cure certain cases of congenital dislocation of the hip. He determines the condition by roentgenograms of the hip, one taken with the patella and foot directed straight forwards, and one with the limb internally rotated. To correct this anteversion, he does an osteotomy of the shaft in the lower third, and puts the limb up in plaster, with the lower portion externally rotated. When the union is complete he reduces the dislocation of the hip.

[Ed. Note.—The Editors believe that the anteversion does not often offer an actual obstruction to complete reduction, and although if this anteversion persisted it would make the reposition less stable, it has been their experience that with complete reduction and careful after-treatment in many instances it corrects itself.]

##### *Club-Foot.*

Cook<sup>28</sup> reports about twenty cases with good results from the removal of the bony wedge from the outer side of the foot. A sufficiently large wedge of bone must be removed, and it is also necessary thoroughly to rotate the front part of the foot to overcome the deformity. Cook keeps the foot in plaster for eight weeks and then uses a foot plate. He considers that the two cases in which a further relapse occurred were due to the insufficient amount of bone removed. He considers the operation is analogous to the work of a carpenter or cabinet maker.

[Ed. Note.—In adults this operation may often be necessary, but in children we doubt the wisdom of removing large wedges of bone. The results are likely to be bad several years later on account of the constant pull of the adducting muscles and the disturbance in growth. One must be careful not to over-correct, because to

make a valgus foot out of a varus is making an equally bad deformity. In adults who wish quick results the operation may be done with much satisfaction.]

#### FRACTURES AND DISLOCATIONS.

##### *Old Patella Fracture.*

Phemister<sup>29</sup> has made an interesting study of the problem which is presented in old fractures of the patella, where the resulting separation of the fragments is very great. It is difficult to get fractured surfaces together, and in some cases the intervening space must be bridged over in order to get a functional hold that may be used by the quadriceps muscle. A fascia transplant taken either from the outer side of the thigh or a pedunculated flap from the thinner portion just above the quadriceps tendon may be used for this purpose. The author recommends occasionally removing the insertion of the tendon from the tubercle of the tibia, but it is not generally advisable on account of the difficulty of securing an attachment higher up. Of course, all adhesions about the joint beneath the patella should be freed.

##### *Delayed Union.*

Henderson<sup>30</sup> has collected 181 cases of fracture of the long bones treated in the Mayo Clinic during the last four years. Sixty-one of these cases were treated for non-union. The operation to obtain union by the use of bone transplants was performed 31 times. This was found to give success in the large majority of cases, although the procedure was not infallible. It is, of course, of special importance that asepsis should be maintained, that an autogenous graft be used, and that it be carefully placed in assured contact with the fractured bones. The inlay method, as developed by Buchanan and Albee, is found much better than the medullary peg. This latter method does not give as firm support, and leaves in the centre of the bone a foreign body to be absorbed. Of the 31 cases, 16 occurred in the tibia. They were of average duration of 12 months, and seven of them had been previously plated. With a circular saw a piece of bone was removed from the flat internal surfaces of the bone and slid into apposition with the other fragments. In all but one of these cases the result was successful. There were seven cases of non-union of the humerus, and the three of these which afterwards were kept fixed in plaster casts showed good results. The cases which showed non-union he explains as follows: in the tibia on account of the use of a poor bone graft; in the humerus on account of lack of fixation; and in the femur on account of an insufficient size of the bone peg for fixation.

##### *Early Knee Motion in Fracture of Femur.*

Ansinn<sup>31</sup> has been impressed with the frequency with which stiff knees and atrophied

museles follow prolonged immobilization in fractures of the femur. He has devised an apparatus which allows early motion of the knee joint, and in 30 cases has been delighted with the results obtained. There was no trace of ankylosis of the knee joint, there was an almost entire absence of atrophy, and firm bony union was obtained in an unusually short time.

[Ed. Note.—The Editors believe attention should be called to this unfortunate and unnecessary sequela of prolonged immobilization in fractures of the femur. The old dictum that prolonged immobilization never stiffens a normal joint would seem not to be sound, unless we conceive the fracture of the shaft of the femur to produce joint changes. Restricted and painful motion in the knee delays very materially return of function in the limb, though union of the fracture may be firm enough to allow the guarded weight-bearing which favors complete solidification. Scudder's simple iron joints, incorporated in plaster at the knee and capable of being set at any angle, accomplish this same purpose well and prevent any lateral or rotary motion of the lower leg which would be likely to disturb femoral alignment.]

#### *Leverage in Reducing Dislocation.*

Cocher<sup>32</sup> has found a crutch with a long cross bar lever attached at its lower end, very useful in reducing recent and old dislocations of the shoulder, elbow, hip joint, and knee. The large amount of force, always under complete control, may be registered by a dynamometer, and as much as 170 pounds can be thus exerted without jar or shock. The necessity for counter traction is thus avoided.

[Ed. Note.—In the groin we should suppose considerable pressure might be fairly safely exerted, with no more dangerous result to be expected than skin rupture, but in the axilla care must surely be taken lest injury to the axillary vessels and nerves be produced.]

#### *Habitual Dislocation of the Shoulder.*

Selig<sup>33</sup> discusses the various methods which have been used in the treatment of habitual dislocation of the shoulder, and emphasizes the importance of the supraspinatus muscle, which immobilizes the humero-scapular joint and is most important for the function of the joint. Duchenne in 1885 first demonstrated that the supraspinatus was an elevator of the arm, and that, furthermore, its action is necessary in order to keep the head of the humerus in contact with the joint cavity while the arm is elevated. Selig believes that the habitual dislocation is mainly due to elongation of the tendon of the supraspinatus, and has worked out an operation (on the cadaver only) designed to give this muscle its normal power, and consisting in shortening the muscle.

#### *Dislocation of Knee.*

Ransohoff<sup>34</sup> reports a case of anterior and external dislocation of the knee (with rotation to

an angle of 90°), due to a fall of 48 feet. There was some interference with the circulation in the leg, although pulsation could be felt in both the dorsalis pedis and the posterior tibial arteries. The dislocation was easily reduced, and function at the end of six weeks was practically restored. Ransohoff says that this is only the third case of dislocation of the knee occurring in a large accident service during a period of twenty-seven years, and that only 250 can be collected from the literature.

#### POSTURE.

##### *Postural Albuminuria.*

Jeanneret<sup>35</sup> remarks that Stirling was the first to call attention to intermittent albuminuria in children in connection with the position of the body, and he styled it "postural albuminuria." Jeanneret declares that this is the best name for it, as neither the orthostatic nor the lordotic attitude ever induce it except in the predisposed. The extreme lordosis, which is induced by Rollier's pillow in heliotherapy of Pott's disease, is borne by children at Leysin over long periods without their developing albuminuria. Jeanneret has also examined other cases of extreme lordosis, and no albuminuria was observed in them at any time. In still further tests, he had all children at the Children's Hospital at Basel lie on Rollier pillows, but albuminuria was scarcely ever observed from the extreme lordosis thus induced. This was the more remarkable as the children in the hospital were all more or less debilitated. On the other hand, 20% of the children in school present intermittent albuminuria. Numerous tests were made in different cases. One child of eleven had no albumin, in bed with milk diet, none in bed on mixed diet, none after three hours of extreme lordosis induced with Rollier cushion, none playing in the garden, and none during one-half hour in the erect posture while she stepped from leg to leg or otherwise exercised the legs. Albumin, however, appeared in the urine in three minutes after the child stood erect in extreme lordosis and kept perfectly still. There was 1% the third minute, 2% the fifth minute, 3% the fifteenth, and 10% the thirtieth minute. Further tests confirmed the importance in the genesis of intermittent albuminuria of this factor, namely, keeping still with the body upright, when this factor was superposed on even moderate lordosis. Of 204 children examined, albuminuria could be induced by lordosis alone in only 3%, and by a change from the seated to the erect posture (orthostatism) only in 1/3%. Both together, the children not keeping still, induced albuminuria in only 1.6%. But the combination of lordosis, orthostatism, and muscular immobility induced more or less albuminuria in 49%. The findings in the various groups are listed in detail in twelve tables. They show that the restlessness of children responds to a physiologic demand, and that children should

not be expected to sit still in school. The school desk should be arranged to avoid inducing lordosis. Jeanneret explains the anatomic and physiologic conditions, with illustrations, which are likely to start the albuminuria, when in children the normal play of muscles and the local circulation are checked by keeping motionless.

#### *Orthostatic Albuminuria in Relation to Nephritis.*

Holst<sup>36</sup> examined post-mortem the kidneys of a youth of 16 who had had typical orthostatic albuminuria during the last five or six years, but who had been otherwise in normal health until he contracted "galloping tuberculosis" of the lungs. Not a trace of inflammation could be discovered in the kidneys. He reports also ten clinical cases in which orthostatic albuminuria was a chronic condition, but in which no tubular casts were ever found.

#### WAR SURGERY.

##### *Gunshot Wounds of Knee Joint.*

Berard and Barjaval<sup>37</sup> believe that expectant treatment in gunshot wounds of the knee joint is justified, provided the case is followed with constant attention by the same surgeon. The function of many joints may be thus conserved, and they have been impressed with the tolerance of the synovia to the presence of bullets or shell fragments. In four cases the projectile was well tolerated for over two weeks.

Lockwood,<sup>38</sup> on the other hand, though strongly urging conservatism in treatment of compound joint injuries, believes that: (1) All foreign bodies, whether metal or loose bone, should be removed from the knee joint at the earliest possible moment. 2. Perfect immobilization is absolutely necessary. Do not start passive movements too early, that is, not until two weeks after the inflammation has disappeared. 3. All necrotic and edematous tissue should be excised. 4. Capsule closed as soon as possible. 5. No antiseptics other than 2% formaldehyd to be introduced into the joint. 6. No drainage tubes against joint surfaces. Out of 60 cases 49 resulted in free motion, 3 in ankylosis, and the others in limited motion.

[Ed. Note.—These results are surely unusually good, and seem to show very definitely that the conservatism and detailed observation in compound joint injuries, which the Editors strongly recommended in a previous Report of Progress in Orthopaedic Surgery, is not only justified, but demanded.]

##### *Bridge Plasters in Treatment of Compound Fractures.*

It is interesting to see the increasing use of plaster-of-Paris casts in the treatment of the severe septic compound fractures, both as a temporary dressing, which gives the soldiers great comfort while they are recovering from shock,

as recommended by S  n  chal,<sup>39</sup> and as permanent and even ambulatory dressings, as advised by Aubert<sup>40</sup> and Lance.<sup>41</sup> Aubert has found them as useful in lesions of the upper limbs, even those including the shoulder, as in the lower limbs, and Lance, by including iron bridges, has left the leg accessible from just above the ankle to above the trochanter, using the pelvis and lower thorax as the upper fixed point.

[Ed. Note.—The adoption by some of the best French surgeons of this method speaks strongly in its favor, for our impression is that early in the war there was a more or less general prejudice in France against plaster of Paris in the treatment of these recent and suppurating compound fractures.]

##### *Artificial Limbs.*

Much careful work is being done at present on the problem of providing inexpensive and efficient artificial limbs or prostheses. The most interesting and valuable articles on the subject which we have seen are those of Dollinger,<sup>42</sup> Brekenfeld,<sup>43</sup> and Natzler.<sup>44</sup>

In order to meet the enormous needs for prostheses or artificial limbs, Dollinger, in his clinic at Budapest, has established a workshop in which he employs wounded soldiers as inmates. He started the workshop in March, 1915, with one man, and employs now [October, 1915, when the article was written.] 108. During these six or seven months more than 1000 artificial limbs and several hundred other orthopaedic apparatus have been made. He emphasizes the fact that patients with amputated legs learn to walk very quickly with their artificial limbs, provided they fit well. If they have been in bed for a long time it takes longer to learn to walk because of the weakness of the muscles, but even among these he has seen several with amputation of both thighs, learn to walk comparatively quickly with the artificial limbs. Dollinger goes into many of the details of his work, and his descriptions are well illustrated.

1. *Prosthesis of lower leg.* If it can be avoided it is better not to suspend the prosthesis by a pelvic belt, nor should it be held on the femur by anything constricting. The prosthesis is made over a plaster model, which is very carefully moulded over the condyles of the femur and tibia. Over this cast a steel plate is made, which is fastened to a leather cuff which is to reach up to the middle of the thigh. The weight-bearing is borne by the condyles of the femur and by the inner condyle of the tibia. The patient does not walk on his stump directly. A plaster cast of the good leg is made for comparison to determine the desirable length, etc.

2. *Prosthesis for amputated thigh.* In very fat patients, Dollinger uses for suspension the customary shoulder belt. In others, however, he suspends it on a girdle, which is carefully modelled over the pelvis, and which reaches about 3-4 fingers' width above the pelvis on the back.

Weight-bearing is, as a rule, not possible or advisable on the stump itself, therefore a kind of seat is constructed over a carefully-made model, in which the patient, as it were, sits on his ischial tuberosity. The model is taken while the subject stands upon the good leg, with slight head extension. A cast is made of nearly the whole trunk, the stump, and the good leg. 3. *Protheses for amputated hands and forearms* are modeled in a way similar to those for the lower leg, that is, over the distal end of the bones of the forearm and the condyles of the humerus.

Brekenfeld<sup>43</sup> describes artificial limbs used by Hoefftmann in Königsberg. After a great deal of experimenting, Hoefftmann has come to the conclusion that a solid foot piece, which, however, is not as long as the normal foot, is best. The jointed feet, as well as those constructed with a rubber pad, do not allow enough stability and safety, especially in going up and down stairs, and the patient loses confidence in his limb. The details of the construction must be seen from the original. During the present war the artificial limbs of Hoefftmann have stood the test in a most excellent manner. The author describes the case of a captain in the army whose femur was amputated, and who is now doing full field duty with an artificial leg made in the workshop of Hoefftmann's clinic.

Natzler,<sup>44</sup> who is an assistant of Riedinger in Würzburg, emphasizes the importance of making for substitutions of lost arms or parts of the arm, not artificial limbs which resemble the shape of the normal arm, but of making what he calls "workmen's protheses." It is important not to make these protheses for the arm too long, but a good deal shorter than the normal arm measurements. The illustrated descriptions of patients who do full duty as mechanics, show how useful these simple apparatus can be,—indeed, much more useful than more elaborate artificial arms and hands.

#### *Wounds of Peripheral Nerves.*

Stoffel<sup>45</sup> believes that the neurolysis (*i.e.* freeing nerves from adhesions, etc.) which is frequently indicated in wounded soldiers, should be undertaken only with a full consideration of the anatomical structure of the nerves. He advises repairing first the motor tracts, and only after these have been sufficiently repaired, the sensory tracts may be considered if it seems wise. The use of a sterilized magnifying glass is very useful. The improvement after neurolysis is sometimes very surprisingly fast. Stoffel has seen cases which showed the first traces of improvement a few days after the operation, though in the majority of cases it takes several months before function is restored. At all events, one should not excise the nerve in its whole continuity before one has studied the nerve tracts.

Stracker<sup>46</sup> reports about 225 operations on

wounded peripheral nerves which have been done between February, 1915, and January, 1916, in Spitzzy's hospital. The operations have been performed by Spitzzy, Erlacher, and the author. Of the 225 cases, 93 were resections; in 39 neurolysis was performed, in 15 a tubularization, and in 4 a grafting. It is of interest to note the great difference in the result after resections in the various nerves. Among 25 cases of resection of the radial nerve, 12 showed recovery of the motility; of 13 cases of the median, 4 recovered; of 13 cases of the ulnar, 3 recovered; of 12 cases of the sciatic nerve, 2 recovered; and of 21 cases of the peroneal nerve, 1 recovered. The results after neurolysis were much better. In some cases a distinct improvement was seen from a few hours up to a few days after the neurolysis.

#### MISCELLANEOUS ARTICLES.

##### *Preventive Orthopaedic Surgery.*

Hardouin<sup>47</sup> has encountered a number of cases in which, after a bullet passed through the calf, the disturbances were so slight that the men were soon on their feet. The traction on the wound, however, caused pain, and in order to prevent this the foot was held in an abnormal position of actual talipes equinus, and as these men were known to be mildly wounded, they did not get the medical supervision of the other wounded. But the deformed attitude of the foot soon became permanent, and they were left cripples unless the deformity was noticed and corrected in time. If they were allowed to use crutches, permanent crippling was almost inevitable. Men with wounds in the legs should not be allowed to be on their feet until the wound is entirely healed. Disregard of this principle makes the healing drag for weeks longer than it should. When they are allowed to walk, the position of the foot should be kept normal, and it should be exercised only a very little at first. Massage is seldom useful, but a plaster cast may be needed in the grave cases.

[Ed. Note.—This observation of Hardouin's is entirely correct and represents one of the great advantages of preventive orthopaedic surgery. The value and economy of this type of anticipatory treatment, based on a knowledge of the sequelae of neglect, can hardly be over-emphasized, and the emphasis should be placed by orthopaedic surgeons.]

##### *Persistent Sciatica Relieved by Förster's Operation.*

Mettraux<sup>48</sup> reports the case of a man of 30, who had suffered more or less from a left sciatica for five years, and whose pain for the last six months had become agonizing, totally incapacitating the patient, and rebellious to all measures, including treatment for syphilis. As a last resort, Förster's operation was proposed, and in October, 1914, through an incision from the second lumbar to the first sacral spinous

process, from 1.5 to 2.5 cm. of the second sacral posterior root and the fifth lumbar were resected. Tamini, of Buenos Aires, has demonstrated that the last large root of the cauda equina is the second sacral root, and that this second sacral root is only half the size of the first sacral, whose diameter is the same as that of the last lumbar roots. The second sacral was thus easily located, and not more than 25 c.c. of spinal fluid was lost during the operation. The patient was kept lying prone for 24 hours, and the stitches were removed on the eighth day. There was then pronounced paresis of the left leg, but no single group of muscles seemed paralyzed, and motor functioning was gradually regained. Two months afterward the patient could take long walks without fatigue, and there has been no return of the pain, and the sciatic is not tender. The patient is said to be "enchanted with the result." Along the back of the thigh and the inner margin of the foot the sensibility is reduced, and there is an occasional burning sensation in the sole of the foot.

#### *Multiple Cartilaginous Exostoses.*

Ashhurst<sup>49</sup> has contributed an interesting paper on multiple cartilaginous exostoses. Cases showing numerous exostoses were described by Ollier in 1899, and mention was also made of them by Hawkins in 1837. Ehrenfried has recently collected 12 cases. The author reports 11 cases. He does not think that the exostoses are an essential feature; the irregular epiphyseal line is the more important characteristic. The epiphyses are small, misshapen, and the shafts of the bones curved. There are nests of uncalcified cells just beneath the periosteum near the ends of the shaft, which later develop into irregular growths which are almost always benign. They usually develop at an age of 12-16 years, and occasionally a second crop appears in later life. Certain of Ashhurst's cases showed definite exostoses developing without cause. Many, however, had a definite trauma, often slight, but still with a local lesion. While Ehrenfried believes the etiology is due to some embryological factor, as a faulty "anlage" for the development of bone, the author considers that these cases represent a certain type of chondrodys trophy, and that the exostoses are generally determined by other factors.

#### *Juxta-articular Sarcoma.*

Roberts<sup>50</sup> states that it is often the case that this type of tumor located in the vertebra or near the hip or knee gives symptoms which resemble pictures of tuberculosis. A careful study of the nerve symptoms and the influence of weight-bearing may differentiate these. Roberts considers the x-ray the most important means of diagnosis. The local pain and local tenderness and the deformity, which does not always correspond to the x-ray picture, are important elements in determining the nature of

the disease. Treatment by fixation often does not relieve the pain, and the absence of bony atrophy and abscesses are further points in differentiating it from tuberculosis.

#### *Pathology of Trench Frostbite.*

Smith, Ritchie, and Dawson<sup>51</sup> have conducted a very practical research into the experimental and clinical pathology of this condition. The exposure of the feet insufficiently clad is undoubtedly the cause of much of all foot troubles and adds to the discomfort of many patients with strained and pronated feet. This is a study of 51 clinical cases of soldiers returning from the front. They had been in the cold, muddy trenches, often in water up to the waist, and suffered from exposure to the rain, sleet and snow; conditions that are sometimes reproduced in the occupations of our laboring class. Most of the cases showed marked swelling, tenderness, sometimes local heat, and considerable disability. It was felt that the part played by tight boots and leggings had much to do with preventing proper circulation. Experiments made with rabbits showed very interesting changes, which offer some explanation of the course of the disease. The essential change in the feet when exposed to the severe cold consists in damage to the blood vessels. After an initial constriction of the vessels passes off, swelling of the feet occurs, while the circulation is being restored to its normal. Microscopically, there is shown a swelling of the lining endothelial cells of the vessels and destruction in the muscle fibres of the walls. Excessive fluid is poured out into the tissues, even though the walls of the vessels may not be ruptured. The resulting stasis interferes with the vitality of the cells in the surrounding connective tissue. Leucocytes and other phagocytic cells appear in the tissue, and a general chronic inflammatory process may take place. The nature of these changes clearly explains the slowness of the recovery. For this to be complete, there must be not only an absorption of the swelling, but a restoration of the vessel walls so that they can stand the strain of the changes in the circulation which take place when the patients begin to walk again; thus it is found that often when the swelling has disappeared, pain, tenderness, and disturbance of function still persist, and any application of extreme cold or heat is apt to bring back the symptoms. Experimentally, they also show the part that is played by pressure and constriction in predisposing the parts to the effects of cold. Very little has been written on the treatment of this condition, but Dr. W. J. Terrell, in the *Practitioner* for January, 1916, speaks of the value of electrical treatment and the use of high frequency in stimulating the circulation in some of these cases.

#### *Spontaneous Gangrene.*

McArthur<sup>52</sup> discusses the treatment of a spontaneous gangrene, termed "trophic gangrene."

itis" by Buerger, and "spontaneous gangrene of the young," by Koga. The condition in this country is almost exclusively found among members of the Jewish race. Mayesima had determined the constant high viscosity of the blood in all cases of gangrene, and acting on this, Koga confirmed Mayesima's findings and reduced the viscosity by diluting the blood with physiologic solutions (Ringer's). Cases which in the past would undoubtedly have been condemned to high amputation, he succeeded in curing by the simple expedient of hypodermoclysis of a sufficient quantity of Ringer's solution and over a sufficient period of time to reduce the viscosity of the patient's blood. McArthur says that the testimony of all those who have faithfully carried out Koga's recommendation verifies his claims.

### *Syphilis of the Spine.*

Whitney and Baldwin,<sup>52</sup> in a study of 100 unselected cases of syphilis, found 36 patients with sharply localized stiffness of a segment of the spine, the remaining portions of the spine being flexible. In these 18 showed hypotonicity. (By this term the authors apparently mean a lack of muscular tone and a laxness of the articulations, allowing freer motion than normal, chiefly in the lumbo-sacral region.) Among 25 patients with localized stiffness and less marked general stiffness, 11 showed hypotonicity. Among 7 patients with uniformly stiff spines, 2 showed hypotonicity. They conclude: (1) That a localized stiffness of the spine is strongly suggestive of syphilis. This was present in over half of this series, and rare in non-syphilitic cases. (2) That localized stiffness of the spine with hypotonicity of the uninvolved spine and the pelvis and hip joints, is almost pathognomonic of syphilis. (3) That a negative Wassermann reaction should not be interpreted as excluding syphilis in the presence of other signs which suggest joint syphilis.

### ORTHOPEAEDIC PREPAREDNESS.

At the annual meeting of the American Orthopedic Association, held in Washington in conjunction with the American College of Physicians and Surgeons, the matter of orthopaedic preparedness was brought up for discussion at one of the executive sessions. It was pointed out that perhaps no specialty in medicine had a possibility of being of more far-reaching usefulness than orthopaedic surgery. Judgment as to the efficiency of the locomotive apparatus of recruits, the prevention of deformity, the problems of immobilization of acute bone and joint injuries, the restoration of function, apparatus for the maimed, the organization of cripple industries, are all matters of peculiar orthopaedic concern. The present war has demonstrated these facts and also unfortunately shown how lacking in preparation along these lines most of

the European governments found themselves at the opening of hostilities. It is most desirable that in America, where orthopaedic surgery is well developed, some form of organization of the orthopaedic resources should at once be undertaken. A committee was appointed, of which Dr. Joel E. Goldthwait was made chairman, to consider methods and means. This matter was also brought to the attention of the Orthopaedic Section of the American Medical Association and a committee with similar aims was appointed, and in order that the two committees might work conjointly, Dr. Goldthwait was appointed chairman of this committee also. The attitude of the United States Government was next ascertained, and a most cordial approval of the plan and a promise of help was received. It seems to the Editors that this committee has an unusual opportunity for usefulness and a great responsibility. Already plans for an orthopaedic base hospital have been outlined, its necessary equipment studied, and the available personnel ascertained. This surely represents progress in orthopaedic surgery and in general medical preparedness.

## Book Reviews.

*A Handbook of Infant Feeding.* By LAWRENCE T. ROYSTER, M.D., Attending Physician, Bonney Home for Girls and Foundling Ward of the Norfolk Society for the Prevention of Cruelty to Children; Physician-in-Charge of King's Daughters' Visiting Nurse Clinic for Sick Babies. Illustrated. St. Louis: C. V. Mosby Company. 1916.

The author states in his preface that the object of this little book is to furnish the essentials, and only the essentials, of infant feeding in a compact and succinct form for the use of the family physician and general practitioner. He follows, in general, the teachings of the Harvard Medical School, advocates the calculation of food mixtures in percentages of the various food elements, recognizes the part which bacteria play in the causation of diseases of the digestive tract in infancy, and emphasizes the value of the examination of the stools as a guide to diagnosis and treatment. His point of view is always sane and reasonable and his explanations clear and simple. This book should, therefore, be of great assistance to those for whom it is written, namely, the general practitioner and family physician.

*Urgent Surgery.* By FÉLIX LEJARS. Translated from the Seventh French Edition by WILLIAM S. DICKIE, F.R.C.S., and ERNEST WARD, M.A., M.D., F.R.C.S. (Third English Impression.) With 20 full-page plates and 1086 illustrations, of which 729 are drawn by DR. E. DALIENE and A. LEUBA, and 198 are from original photographs. Vol II. The Genito-Urinary Organs; The Rectum and Anus; The Strangulated Hernias; The Extremities. New York: William Wood and Company. 1915.

The second of Lejars' two volumes is a book of some 600 pages and, like its companion, is excellently printed, and profusely and effectively illustrated.

The work strikes the reviewer forcibly as a treatise on Operative Surgery, thinly disguised by the word "Urgent." Certainly, almost every operative method is considered, and usually adequately described, including such measures as perineorrhaphy, hematocolpos, operations for simple fracture of the patella and other simple fractures, wounds of nerves, etc. It is somewhat paradoxical that the work should not have been a little more complete, and described by a less restricting title.

The work strongly reflects the opinion and habits of the writer. Citations and quotations are few, very few indeed, from America. It is somewhat of a shock to read in the chapter on

Dislocation of the Hip, "This method, which was originally employed by Després père and afterwards systematized by Bigelow," and to discover that no mention is made of the inverted Y-ligament, either in print or in picture.

The descriptions are brief and accurate; the practice and operative methods at times seem strange to Americans.

The book is an admirable presentation of French views in operative surgery, very suggestive, and valuable as a reference.

*The Principles and Practice of Perimetry.* By LUTHER C. PETER, A.M., M.D., F.A.C.S., Illustrated. Philadelphia: Lea and Febiger. 1916.

This book ought to receive a warm welcome from ophthalmologists. As far as we know, there is no single volume in English on Perimetry. There is room for one, and Dr. Peter's work has admirably supplied this want. The book is full enough to be worth while without being tiresome. It is a systematic study of perimetry, its principles and practice. Various devices for taking fields are described, but the author devotes most of this part of his work to practical office methods, and many of us can learn something here. Anatomy, physiology and general pathology of the visual field are given space enough, while the second half of the volume treats of special pathology of fields. The field in functional nervous diseases is the subject of the last chapter. A bibliography, mostly confined to the last decade, is given and an excellent index.

*The Nose, Throat and Ear, their Functions and Diseases. A Treatise upon the Breath-Road, Food-Road and Accessory Organs.* By BEN CLARK GILE, M.D., Instructor in Otology in the University of Pennsylvania. With 131 illustrations. Philadelphia: P. Blakiston's Son & Co. 1915.

This is a book of 450 pages intended to give the more important facts of etiology, pathology and treatment of diseases of the nose, throat and ear. Many of these facts are well stated, but this is not always the case. For instance, in the brief chapter on laryngeal neuroses, the following assertions appear, "The nerves of the larynx are the superior laryngeal whose function is motor, and the inferior, or recurrent laryngeal which conveys motor and also sensory impulses." "The arytenoid and cricoarytenoid muscles are the adductors of the vocal cords." The modern theory that vaso-motor rhinitis is an anaphylactic reaction to certain proteins is entirely ignored. Ready reference is much impaired by the lack of subdivisions, making it necessary to refer constantly to the index. The book is brightened by an occasional descriptive exposition of frailties of human nature, both lay and medical. It contains no legends, and is an attractive manual more desirable than didactic notes for a student.

*The Mortality from Cancer Throughout the World.* By F. L. HOFFMAN. Published by the Prudential Insurance Company of America, 1916.

A readable statistical study is rare. This work is not only very readable, but also the valuable information gathered is set down in an interesting and concise manner.

The author recognizes the difficulties of gathering accurate statistics on a subject so variously termed as cancer, and states that he wishes his work to be considered subject to such necessary errors as one must encounter in such a broad work. The work contains in every chapter a valuable bibliography of the most important books reviewed, and often brief abstracts of these works are given in order to make the text more explicit. The menace of cancer is emphasized and proof brought forward to substantiate the recently expressed view that cancer is not only relatively, but actually, on the increase. The importance of a world-wide educational campaign is emphasized. Several chapters are devoted to such practical topics as the mortality of cancer in different occupations, cancer in its relation to life insurance, statistical studies of cancer in American cities and foreign countries, racial cancer, precancerous states, problems of recurrence, degree of malignancy of certain types and under certain conditions, the question of heredity, relation of cancer to other chronic diseases. All these are treated in an interesting but general way. The work contains about 200 pages of text and 600 devoted to charts and tables. It is a well-compiled, up-to-date and well-presented work, which must have involved great labor and is a worthy and valuable book of reference.

*The Endocrine Organs.* An Introduction to the Study of Internal Secretion. By SIR EDWARD A. SCHAFER, LL. D., D.Sc., M.D., F.R.S. Professor of Physiology in Edinburgh University. London and New York: Longmans, Green and Company.

In the summer of 1913 Professor Schafer delivered the Lane Medical Lectures at Stanford University. He took for his topic the organs of internal secretion. The lectures were published by the University, but in abbreviated form and without illustration, so the author has reissued them in the present volume.

The work consists almost wholly of descriptions of experimental and clinical observations. Conclusions are drawn cautiously or not at all, as is eminently proper in a field in which, on account of the rapid accumulation of data, conclusions are necessarily wholly provisional. The numerous excellent plates add greatly to the value of the book, as they do to its cost.

*The Involuntary Nervous System.* By WALTER HOLBROOK GASKELL, M.A., M.D., F.R.S. London and New York: Longmans, Green and Company.

To the serious student no form of presentation of any special subject is more satisfactory than an authoritative monograph. The publishers of the work here under review have made a feature of series of such monographs in various fields of science, and in so doing have conferred a great benefit upon students everywhere.

This work of Professor Gaskell's, prepared during the closing years of his life and published posthumously, is an epitome of a course of lectures on the sympathetic and allied nervous systems, given by the author year after year. It represents in very large measure his own contribution, since he took a prominent part in the development of our present conceptions concerning these portions of the nervous system, particularly in their earlier stages. Professor Gaskell was specially interested in the phylogenetic significance of physiology, and much of the value of this work lies in the discussions of the bearing of the facts presented on the principles of evolution. It is unfortunate that Professor Gaskell did not live to see the remarkable clarification of our views concerning the sympathetic system, that has resulted from the researches of Cannon and his students. No one would have appreciated more than he the significance of Cannon's correlation of the entire sympathetic system into an integer.

A valuable feature of the book is the bibliography, which covers 13 pages and includes all the important titles up to 1914.

*Blood Pressure.* Its Clinical Applications. By GEORGE WILLIAM NORRIS, A.B., M.D. Second edition, revised and enlarged. Philadelphia and New York: Lea and Febiger. 1916.

The first edition of this clinical text-book on blood pressure was reviewed in the issue of the JOURNAL for November 12, 1914 (Vol. clxxi. p. 755). This second edition is increased in size by the addition of new material from the constantly growing literature on this important subject; but the author has continued his endeavor to present this material in condensed and practical form. Whenever possible, a summary of experimental as well as of clinical data is included. In addition to the chapters on physiology and on venous blood pressure by Dr. J. Harold Austin there is appended a chapter on functional efficiency of the circulation, in the preparation of which Dr. Austin's assistance is also acknowledged. The number of engravings with which this edition is illustrated is increased to 102. It should continue to maintain its position of value as a presentation of the literary history of the subject and as a correlation of experimental data with clinical experience.

# THE BOSTON Medical and Surgical Journal

Established in 1812

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

**SUBSCRIPTION TERMS:** \$5.00 per year, in advance, postage paid, for the United States. \$6.50 per year for all foreign countries belonging to the Postal Union.

An editor will be in the editorial office daily, except Sunday, from twelve to one-thirty p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish one hundred reprints free to the author, upon his written request.

The Journal does not hold itself responsible for any opinions or sentiments advanced by any contributor in any article published in its columns.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, Manager,

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

## PROGRESS OF THE POLIOMYELITIS EPIDEMICS.

DURING the past week the various epidemics of poliomyelitis in the United States, though still active, have seemed to show a definite tendency to decrease. In New York City, on August 30, the number of cases reached a total of 7,986, with 1,911 deaths. In New York State, outside the city, the total of cases on that date was 1,620, with 166 deaths.

The second largest focus of the disease is in New Jersey, where the total number of cases has been 2,163, with 205 deaths. The other principal epidemics are in Pennsylvania, Connecticut, Massachusetts and Rhode Island. In Chicago there have been 85 cases; in Connecticut, 352. The northern New England states have been practically immune from the disease, there having been 14 cases in Maine, only 3 in New Hampshire, and none in Vermont.

The Massachusetts epidemic as yet has not attained the proportions of the two serious epi-

demics of 1909 and 1910. The number of cases of poliomyelitis in this state during the past eight years has been as follows: 136 in 1908, 923 in 1909, 845 in 1910, 232 in 1911, 169 in 1912, 361 in 1913, 151 in 1914, and 135 in 1915. The total of cases in Massachusetts in August, 1916, is 248, of which 221 have been in North Adams.

In the issue of the JOURNAL for August 24, we noted editorially the national conference of state and territorial officials which was held on August 17, in Washington, D. C., under the auspices of the United States Public Health Service, to standardize methods of combating poliomyelitis throughout the country. Representatives of 38 states were present at this conference, whose decisions related chiefly to the establishment of uniform interstate quarantine and travel restriction. It was decided that every child under 16 must have a certificate of travel without which it must not enter or leave the state of its residence. Any children entering another state without such a certificate are to be placed under quarantine. This certificate of travel is to state the name of the place from which the child is traveling, its intended destination, and the local prevalence of poliomyelitis. This certificate is not a guarantee of immunity, nor does it exempt its possessor from examination by a physician and observation for a fortnight in the place to which the child goes. It is hoped that the adoption of these provisions through the greater part of the United States will result in checking further extension of the disease and the establishment of new foci.

Following the Washington conference, a further conference of New England health officials was held in Boston, at which representatives were present from Maine, New Hampshire, Massachusetts and Rhode Island. These representatives were Dr. A. G. Young, Secretary Maine State Board of Health, Dr. Allan J. McLaughlin, and Dr. Eugene R. Kelley of the Massachusetts Health Department, Dr. Gardner T. Schwartz, Secretary of the Rhode Island State Board of Health, and Dr. Francis X. Mahoney and Dr. T. B. Shea of the Boston Health Department. This conference voted to permit, in New England, free passage of persons from any state through another, provided these persons come from uninfected houses or premises. Perhaps the only amusing feature in this present serious visitation has been the setting up at Chinatown, in Boston, of a large dragon whose presence, the residents believe, will avert the local incidence of poliomyelitis.

In the issue of the *Journal of the American Medical Association* for August 19, is published an important note by Dr. Simon Flexner on the serum treatment of poliomyelitis, to which reference has been made in recent editorials in the JOURNAL. Dr. Flexner summarizes the history of the serological study of poliomyelitis and the steps previously taken in the experimental serum therapy of the disease. Finally, he cites the work of Netter and Salanier, published in the *Bulletin of the Academy of Medicine*, for October 12, 1915, and the *Bulletin of the Medical Society of the Hospitals of Paris*, for March 10, 1916. In reviewing Netter's work Dr. Flexner says:

"Netter was the first to apply the data obtained by experiments on monkeys to the treatment of cases of epidemic poliomyelitis in men. He had published the results obtained in a small series of 35 cases which he regarded as highly favorable to the method.

"He employed the serum from cases of poliomyelitis in which complete recovery from the acute condition had taken place some time—even as long as 30 years—previously. The serum injections were given subdurally as soon after the appearance and recognition of the symptoms of poliomyelitis as possible."

The serum is, of course, sterile, and need not be inactivated. Its dosage is determined by the age of the patient and by the quantity of the serum available. Initial doses of from 5 to 20 c.c. may be employed and repeated several times at daily intervals, according to clinical conditions and indications. The effects of the immune serum are to be sought in checking the progress of the disease, that is, in the prevention or minimization of the paralysis when given in the pre-paralytic stage and in the arrest of its extension when given in progressive paralytic conditions.

"Since the immunity substances have been determined by neutralization tests to persist in the blood for many years, it is probable, as Netter has indicated, that persons who have passed through an attack of poliomyelitis many years earlier, may be utilized as sources of the serum. Reasoning from analogy it would probably be advantageous to prefer persons whose attacks were less remote so as to insure as high concentration of the immunity bodies as possible.

"In choosing the person who is to serve as the source of the blood from which the immune serum is to be derived care should, of course, be taken to secure a healthy donor."

Dr. Flexner's authority in poliomyelitis is

unique and with his endorsement following upon the successful results reported by Netter and Salanier it may be expected that serum therapy now offers the best, and perhaps a completely controlling, therapeutic measure in poliomyelitis.

## THE MEDICAL KNOWLEDGE OF CERVANTES.

IN last week's issue of the JOURNAL, we commented editorially on certain medical aspects of Shakespeare's genius, and briefly reviewed some of the recent literature bearing upon this subject. It should not be forgotten that this year is equally the tercentenary of the death of Miguel de Cervantes, to whose creative power we owe, in Don Quixote, a character almost the equal of Falstaff, and whose interest in medicine is reflected in many passages of his great work.

Doubtless in his case this interest was partly hereditary, for Rodrigo de Cervantes, his father, was a surgeon apothecary. Miguel himself, born in 1547, entered the Spanish navy, then the most powerful in the world and offering to young men an attractive career of adventure. It is narrated of him that at the Battle of Lepanto he lay ill of a fever aboard his ship, the *Marquesa*, but insisted on going above to fight. He received two gunshot wounds in the chest, and a third which permanently disabled his right hand. Perhaps his personal surgical experience at this time, and later as a Moorish captive, further increased his knowledge of the medical profession, upon which many Spanish authors have written.

In the issue of the *British Medical Journal* for May 20, 1916, was published the following editorial comment on the medical knowledge of Cervantes as evidenced in various of his works:—

"Cervantes mentions about a hundred plants, describing their medicinal and alimentary uses, and he is acquainted with the great compilation of Dioscorides on materia medica, at least in the Spanish translation of Andrés Laguna of Segovia, physician to Charles I (afterwards the Emperor Charles V) and Philip II. He had also read Pliny's *Natural History*, then held in Spain, as it was in England at that day, as of high authority on all things medical. He speaks of poisons which breed madness in men's brains, and discharges shafts of satire at druggists and doctors, but it is only pretenders and impostors at whom they are aimed.

"In more than one passage Cervantes scoffs at secret and superstitious remedies. When Don Quixote is losing blood after a fight, he re-

grets that he has not by him the Balsam of Pierabras, a medicine of such potency that if his body were cloven in twain, one part could be accurately adjusted to the other 'before the blood congeal,' when two draughts would make him 'sounder than an apple.' This balsam was believed to be a part of that used by Joseph of Arimathea to embalm the body of Christ. Elsewhere Sancho prepares for his bruised master a compound of simples, over which he says a number of Paters, Aves, Salves, and Credos, with many signs of the cross.

"Cervantes makes some unmistakable allusions to venereal disease. In *El Casamiento Engañoso* there is a description of an unfortunate officer leaving hospital where he had sweated away fourteen loads of buboes. In the same work mention is made of a disease called *lupicia* (alopeia) or *pelareta* (from *pelar*, to pluck out hair), treated by sweating, which makes all the hair, including the eyebrows, eyelashes, and beard fall out. The scene of the *Coloquio de los Perros* in the *Novelas Ejemplares* is laid in the Hospital of the Resurrection at Valladolid. In many places Cervantes dwells on the hygienic value of plain diet and moderation in eating. Delightful fun is made of the dietetic crank, Dr. Pedro Recio de Agüero, who stands beside Sancho when he is at table and condemns the various dishes set before him—one as being too moist, another too heating, and so forth, till the starving governor of Barataria threatens to knock him on the head with the chair on which he is sitting, saying that if he is charged with murder he will plead in excuse that he has rendered a service to God by killing a bad doctor.

"It was disease of the mind which most interested Cervantes, and Pi y Molist has written a book on him as a medical psychologist. If Cervantes does not bring so many mad folk before us as Shakespeare, he gives in *Don Quixote* the most finished picture in all literature of a certain type of insanity. Much reading of romances of chivalry had made the Knight of the Sorrowful Countenance mad. On all other subjects he was of good understanding and could discourse rationally. Cervantes speaks of hallucinations of smell which make the Don describe as an aromatic fragrance the odor diffused by his Dulcinea. He also refers to the loss of memory which makes the Knight exaggerate his adventures as caused by continual and extraordinary labors. The methods by which those about him seek to divert his mind from the exalted ideas which had led him to go about in search of adventures show that his creator had a clear notion of the value of moral treatment. The last illness of Quixote, in which he passes from madness to profound melancholy and recovers his reason with the onset of fever, may be compared with the death of Lear. Sancho Panza is an example of what Charles Lamb calls the 'twilight state of insanity, the madness at second hand, the contagion caught from a stronger mind infected.' In *El Licenciado Vidriera* Cervantes

gives a picture of madness brought on in a student of Salamanca by a love-philtre, such as is said to have caused the death of Lucretius. The young man imagined that he was made of glass from head to foot; when any one came near he would call upon him with terrible cries to keep away, lest he should be broken.

"In the 'Colloquy of the Dogs' we get a glimpse of the overcrowding of the medical profession in Cervantes' day. A student of Alcalá is quoted as saying that of the 5,000 students in that university 2,000 belonged to the medical faculty. The comment on this remark is that either all these doctors would require to have sufficient patients to cure—which would be a terrible disaster—or they must die of hunger. This makes one think of Abernethy's exclamation, on entering the crowded theatre of St. Bartholomew's on the opening day of a winter session: 'God help you, gentlemen! What is to become of you all?'"

#### A MATERIALISTIC VIEW OF MENTAL DISORDER.

*Mens sana in corpore sano* is a sufficiently euphemistic doctrine to be quoted frequently; this in spite of the fact that the exceptions are at least as prevalent as the rule. Those physicians who are attached to institutions for the insane know cases of men of magnificent physique who are imbeciles. These patients live sometimes to a ripe old age and when they finally die, say of Bright's disease or pneumonia, aside from the actual cause of death and some normal senile changes, no pathological changes may be found. On the other hand, how many absolutely healthy men physically do we meet daily? especially if we are thrown in contact with a class engaged in sedentary occupations. Every pathologist will tell you of the frequency of disease discovered only post-mortem. A normal kidney in an adult is a *rara avis* and we all have tuberculosis more or less.

We can sympathize with those investigators who seek for the causes for such mental disorders as dementia precox and the manic depressive group in physical disturbances, especially when they approach the subject in a scientific spirit and with an open mind; but attempts to correlate anatomical findings and mental symptoms which have little or no apparent connection are less open to sympathy.

The colon as the source of all evil appears again in the columns of the *Lancet* for June 21

Dr. Rupert Farrant reports results of his investigations on lunatics. His studies were particularly of the endocrinous glands, the colon and the faeces. As is the case in most English contributions to psychiatry, the terms used are the older ones, designating disease groups which have been later separated into component parts or merged into other groups with which they really belong, so that we are not always sure of an agreement even in essentials. Thus Farrant speaks of primary and secondary anæmia, acute confusional mania and melancholia. He also shows a tendency to be extremely indefinite in his statements as to what he really found. Thus he says, "In dementia præcox an alteration was found in the glands which varied with the duration of the case." He does not say the nature of the alteration,—what glands were involved, how these changes "varied with the duration of the case," what percentage of the cases showed such changes and how these changes compare with the condition found in the same glands in mentally normal individuals. His other statements are similarly general and his deductions therefrom are certainly open to question, especially in view of the data presented.

He states for instance: "Cases of dementia præcox exhibit a polyglandular syndrome and different gland types are to be found, and the appearances of the cases vary whether the gland is hypertrophic or atrophic." The only apposite statement which he had made before the generalization is this (besides the one quoted above).

"The pituitary gland was found sometimes to have given rise to symptoms of hyperpituitarism, to apituitarism in idioey, dementia præcox, and other forms of insanity."

Farrant concludes by saying that the treatment now becomes obvious, which it certainly does, providing only that the etiology is correct. He has started to work with a number of cases at the Bethlehem Hospital, beginning with medical and surgical treatment directed to the glands and the colon and, where the former have degenerated, glandular therapy is to be exhibited. We await his results with interest, but with pardonable pessimism. His theories of mental disorder have a familiar ring to them; they savor somewhat of the age when the conception that a physical condition could be due to a psychic cause was unconceivable, although then as now men are quite ready to admit a psychic effect of a physical cause.

## MEDICAL NOTES.

**PREVALENCE OF MALARIA PELLAGRA, SMALL-POX AND TYPHOID FEVER.**—The weekly report of the U. S. Public Health Service for August 18, states that during the month of July, 1916, there were in Arkansas 700 cases of malaria, 113 of pellagra, 45 of smallpox, and 64 of typhoid fever. During the same period there were in Wisconsin 52 cases of smallpox and 59 of typhoid.

**THE BUBONIC PLAGUE AT BRISTOL.**—Report from Bristol, England, on August 17, states that 3 cases of bubonic plague have recently occurred in that port.

**FUND FOR UNIVERSITY OF PENNSYLVANIA HOSPITAL.**—Report from Philadelphia on August 24 states that the University of Pennsylvania Hospital is to receive a fund of over three million dollars bequeathed in 1908 by Anna J. Jeans, for the treatment of cancerous, nervous and disabling disorders.

**HEALTH INSURANCE.**—Compulsory health insurance for wage-earners, which is now being strongly advocated in this country, is pretty certain to be given advancement by the adoption of the measure as a plank in the platform of the national liberal party of Canada, led by Sir Wilfrid Laurier. Compulsory insurance, with provision for contributions from the state, employers and employees, has already been established in Germany, Austria-Hungary, Russia, Great Britain, Holland, Norway, Rumania and Servia. The new Canadian plan includes maternity benefits. There is considerable expectation that the conservative party will follow the liberal lead and that legislation will follow soon after the war. A model bill for the United States has been drafted by the American association for labor legislation and will be introduced next year, the association announces, in 20 state legislatures.

**MIRAMICHI HOSPITAL.**—Report from Newcastle, N. B., on August 24, states that the new Miramichi Hospital in that city, founded by Mr. Ernest Hutchinson of Douglastown, was formally opened on July 1.

"It is the largest and most completely equipped hospital in the maritime provinces. The building is of Miramichi sandstone and has a frontage of 144 feet, with an average width, exclusive of verandahs, of forty feet. It is of three stories besides a full-sized basement, eleven feet one inch from floor to ceiling. Its furniture is of the best that could be procured and the sanitary arrangements are perfect. There is a Wappler x-ray machine with all the latest appliances. The sterilizer is a Bramhall Deane. The kitchen, staff's dining room, and x-ray and dark room, emergency room, boiler and fuel rooms, laundry, janitor's apartments, etc., are in the basement. The partitions and ceiling are all fire-proof.

The ground floor contains two public wards, male medical and female medical. These wards are each 24x28 ft. with twelve-foot ceilings, and contain six beds each. On this floor, to the right of the staircase and elevator, are the main office and the board of trustees' office, while to the left are the general waiting room and the nurses' parlor. Just across the hall is the matron's private room. The corridors are the full length of the central part of the building, and are divided from the wards by brick fire walls with self-closing fire doors, thus making three distinct compartments on each floor. In case of fire one may easily be closed from the other.

The second floor contains two public wards exactly like those on the ground floor, but which will be used as male and female surgical. On this floor, also, there are seven private rooms, each fitted with private baths and fireplaces.

All of these rooms have easy access to spacious verandahs, two stories in height, each floor being 16x33 ft., and overlooking the river.

The third floor is the home of the nurses, and contains the operating department. This department has all the latest conveniences and appliances, sterilizing and anesthetic rooms, etc. The operating room and the many bath rooms and toilets are fitted up with petrosilo floors and walls. The doctor's room has a shower bath and steel lockers. There are two fire escapes, one at each end, running from top story to the ground. There is an observatory on the roof."

THE SENATE COMMITTEE on Public Health and National Quarantine has reported favorably the bill to promote the efficiency of the United States Public Health Service. The bill has already passed the House of Representatives. The bill limits, according to the *Journal of the American Medical Association*, the appointment of the surgeon-general of the Public Health Service to commissioned officers in the service, not lower in grade than surgeon, and requires that the surgeon-general, at the expiration of his four-year term of office, be earned as an extra number in the grade of assistant surgeon-general, unless he be reappointed. As an inducement to physicians to enter the service, the bill provides for the promotion of assistant surgeons to the next higher grade after three years' service, instead of after four years, as at present. The chiefs of the bureaus of zoology, pharmacology and chemistry in the hygienic laboratory are to be commissioned by the President, by and with the advice and consent of the Senate, as professors of zoology, pharmacology and chemistry, respectively, and are to be entitled to leaves of absence as now provided by law for commissioned medical officers. Provision is made for the appointment of five additional professors, qualified for special work in sanitary engineering, epidemiology, pathology, anatomy, bacteriology, housing, or other matters that relate to the propagation and spread of disease. Men of this class, the committee's report,

says, often do not have medical degrees, and under the present system of commissioned service only doctors of medicine are provided for; and the bill will remove this defect and make places for men who are specially trained in these highly technical fields, but who are not graduates in medicine.

UNITED STATES PUBLIC HEALTH SERVICE.—Congress has recently made an appropriation for 33 additional Assistant Surgeons in the United States Public Health Service. These officers are commissioned by the President, and confirmed by the Senate. The tenure of office is permanent, and successful candidates will immediately receive their commissions.

After four years' service, assistant surgeons are entitled to examination for promotion to the grade of passed assistant surgeon. Passed assistant surgeons, after twelve years' service, are entitled to examination for promotion to the grade of surgeon.

Assistant surgeons receive \$2,000, passed assistant surgeons \$2,400, surgeons \$3,000, senior surgeons \$3,500, and assistant surgeon-generals \$4,000 a year. When quarters are not provided, commutation at the rate of \$30, \$40 and \$50 a month, according to the grade, is allowed.

All grades receive longevity pay, 10 per cent., in addition to the regular salary for every five years, up to 40 per cent. after twenty years' service.

Examinations will be held every month or so in various cities, for the convenience of candidates taking the examination. Further information will be furnished by addressing the Surgeon-General, United States Public Health Service, Washington, D. C.

#### EUROPEAN WAR NOTES.

A BRITISH RED CROSS UNIT IN SERBIA. Members of the American medical profession, who were interested last year in the work of Dr. Richard P. Strong and his Typhus Fever Commission in Serbia, will be interested also in a recent publication\* describing the simultaneous work in Serbia of a British Red Cross Unit. This unit was recruited from the Royal Free Hospital of London by Mr. and Mrs. Barry, both physicians, who commanded it. The story of the unit is summarized as follows by a reviewer in the *British Medical Journal*:—

"On arrival it was sent to the chief watering place of the country, Vrnjataska Banja, and given a disused hydropathic establishment and a school; 100 beds were at once established, but eventually the unit controlled six hospitals with 360 beds, and there was also a British Red Cross Unit in the town. The worst misfortunes of Serbia had not then begun, the chief and very serious danger was typhus fever. Consequently the first task was to improve the sanitary

\* *The Serbians and the British Red Cross Unit in Serbia*, by Mrs. Barry, London, 1915.

and destructors and to attend to the sanitary policing of the surroundings; fortunately Austrian prisoners were numerous and proved willing helpers. In his plans for the prevention of the dissemination of typhus fever Mr. Berry went whole-heartedly on the assumption that typhus fever is carried by lice and lice only, and the fact that the measures he took, though improvised and in some respects of a summary kind, were completely successful is important evidence of the truth of that theory. One of the hot springs was used for cleansing all patients admitted, and a state coffee-house near by was used as a receiving hospital, where patients were kept for a few days after the bath. On leaving the bath, the patient was given clean hospital clothes, his own having been taken away for disinfection—by boiling whenever this could be carried out without utterly destroying them, the remainder by sulphur fumigation. A wooden barrack was built for patients who developed typhus either in the receiving hospital or in the general hospital.

"When Serbia was overrun the members of the unit had the good fortune to fall into the hands of the Austro-Hungarians,—their actual guardians were Hungarians, by whom they were well treated, and eventually sent home by way of Switzerland. The book is a joint effort, to which several members of the unit have contributed one or more chapters, and is therefore unequal, but is interesting throughout, and the chapters by Mr. Berry and by Dr. Helen Boyle very well written. Many tributes are paid to the courtesy of the Austrian captors, and as an illustration of this, as well as for the light it throws on a principle of Red Cross law, we may quote the following passage (by Mr. Berry):

"In fact, our treatment by the Hungarians throughout our captivity bore out a little remark made to us once when we were discussing with a Hungarian officer our position as a Red Cross unit in enemy hands. He admitted that we were technically neither 'prisoners of war' nor 'interned.' In reply to the conundrum, 'Then what are we?' he answered, 'Let us say guests.' And as the Austro-Hungarian authorities supplied us with rations, left us our stores, and asked very little of us in return, 'guests' was perhaps a description not so very far wide of the mark."

HONORS FOR BRITISH SURGEONS.—It is reported that the British Military Cross for conspicuous gallantry and devotion to duty has been awarded to Dr. John Moir MacKenzie, who received his medical degree from Aberdeen University in 1915 and immediately entered the Royal Army Medical Corps.

"Though wounded in the foot and arm, he refused to go to hospital, and four days later, during a heavy hostile bombardment, he went up through the enemy artillery barrage, and attended many wounded men, though in considerable pain himself."

The Victoria Cross has been awarded to the late Dr. John Leslie Green of the British Royal Army Medical Corps for most conspicuous devotion to duty.

"Although himself wounded, he went to the assistance of an officer who had been wounded and was hung up on the enemy's wire entanglements, and succeeded in dragging him to a shell hole, where he dressed his wounds, notwithstanding that bombs and rifle grenades were thrown at him the whole time. Capt. Green then endeavored to bring the wounded officer into safe cover, and had nearly succeeded in doing so when he was himself killed."

HONORARY DEGREE FOR CAPTAIN KOENIG.—Report from Amsterdam by way of London on August 26 states that the University of Halle has conferred the honorary degree of M. D. on Captain Koenig of the German submarine *Deutschland* "for having broken the enemy's blockade, thereby enabling the German medico-chemical industry to recover its world position."

MAY A SOLDIER REFUSE TREATMENT?—There is now being tried before a court at Tours the case of a French soldier who refused to receive the electrical treatment ordered for him by his surgeon. In this case the soldier, a Zouave, set upon the surgeon and beat him with his fists. The real question is, however, whether a soldier has the right to refuse to accept treatment ordered by his superior officer. The decision of the court will be awaited with much interest inasmuch as the principle involved will affect thousands of individuals.

CANADIAN RED CROSS.—The recently published eighth annual report of the Canadian Red Cross records the work of this society during 1915 at home, in England, and in the several war zones.

"As regards the work in England, which is under the able direction of Colonel C. A. Hogdgets, C.A.M.C., the Duchess of Connaught Red Cross Hospital, in Major Astor's park overlooking the Thames at Cliveden, under the command of Colonel Gorrell, C. A. M. C., of Ottawa, has accommodation for 900 patients, and the King's Canadian Red Cross Hospital at Bushey Park for 300. The Peak Hydro, at Buxton, has been taken over by the society and converted into the Canadian Medical Services Special Hospital for rheumatism; and as the need was felt for more hospital accommodation for officers a house in Hyde Park Place, London, was obtained through Colonel and Mrs. Gooderham of Toronto, who paid for the equipment and alterations necessary to convert this residence into the Daughters of the Empire Canadian Red Cross Hospital; the cost of maintenance of this hospital has been undertaken by the Canadian Militia Department. The society has also given material assistance to a number of other hospitals and institutions in England and France and to the military hospitals established in

*German Relief Fund*—For German sufferers. Dr. Rudolph Hertz, 32 India street, Boston.

*Italian War Relief*—Lee, Higginson & Co., 44 State street, Boston.

*Jewish Relief*—Harry Fischel, 63 Park Row, New York.

*National Allied Relief Committee*—Lee, Higginson & Co., 44 State street, Boston.

*Polish Relief Fund*—To relieve the war sufferers of Poland. W. P. Blake, 27 Kilby street, Boston.

*Prince of Wales National Relief Fund*—For destitute non-combatants of England. R. M. Stuart Wortley, 25 Broad street, New York.

*Prisoners of War Relief (Teuton)*—Transatlantic Trust Co., 67 William street, New York.

*Prussian Fund*—Hubert Cillis, 50 Union Square, New York.

*Russian War Relief Fund*—For Russian war sufferers. Mrs. Curtis Guild, 124 Marlboro street, Boston.

*Secours National*—For the relief of the French women and children. Mrs. Whitney Warren, 16 East 47th street, New York.

*Serbian Distress Fund*—John F. Moors, 111 Devonshire street, Boston.

*Syrian Relief Fund*—Charles R. Crane, 70 Fifth Avenue, New York.

WAR RELIEF FUNDS.—On September 2 the totals of the principal New England relief funds for the European War reached the following amounts:—

Belgian Fund.....	\$150,177.49
French Wounded Fund....	115,523.94
Armenian Fund.....	66,461.10
French Orphanage Fund...	61,453.83
Surgical Dressings Fund..	45,206.37
Polish Fund.....	42,384.07
Italian Fund.....	21,712.54
Prince of Wales Fund....	14,526.74
Permanent Blind Fund....	4,358.81

#### MEXICAN NOTES.

RED CROSS PREPAREDNESS.—It is exceedingly gratifying to the American Red Cross to be able to announce to the public and its members:

That during the six months ending July 31, 1916, its membership has increased from about 27,000—which represented the growth of the society during ten years following its reorganization in 1905—to about 210,000,—an increase of nearly 800% in its membership in the last six months.

That in this same time the number of Red Cross chapters organized throughout the country has increased from 110 to 199.

That while up to six months ago practically nothing had been done towards organized Red Cross preparedness for furnishing volunteer aid to the sick and wounded of our Army and Navy

in time of war, during the last six months the personnel required for 25 base hospitals of 500 beds each for the Army have been selected and enrolled from among the staff of 25 of the largest and best hospitals of the country; that several Naval base hospitals which are about half the size of the Army base hospitals are now being organized; that funds for the purchase of equipment for 16 of the 25 Army base hospitals, costing \$25,000 each, have been subscribed, and that the purchase of the material for these base hospital units has been begun and the equipment as purchased is being stored so as to be ready for immediate use in case of need.

That in addition to this organization of base hospital units, the personnel required for two field columns, for transferring the sick and wounded from the transfer hospitals for the regular Army medical service to the Red Cross base hospitals, have been selected and enrolled from among the staff of two of the important hospitals of the country and \$10,000 toward the purchase of the equipment for one of these field columns has been subscribed.

While this really wonderful progress during the last six months is most gratifying to the American Red Cross, and while the Red Cross is more than glad to be able to extend its heartiest congratulations to all its members who by their interest and zeal and their united and untiring efforts have secured this progress, it firmly believes that this great showing and success should be but an added incentive to greater effort and greater success, if possible, in the future. For it should ever be remembered by every patriotic American citizen interested in humanity's cause, that even with this great stride to the front, the American Red Cross is still far behind the standard set by little Japan which with its 40 millions of inhabitants has a Red Cross membership of 1,800,000, with an endowment fund of \$13,000,000; while the United States with 100 million people has even now a Red Cross membership of only about 210,000, with an endowment fund of about \$1,000,000.

UNITED STATES HOSPITAL TRAIN.—Report from Chicago states that on August 15, the first hospital train built for the United States left that city for San Antonio, Texas.

The train, consisting of 10 coaches, has been built especially for army work, and is said to be as modern in equipment as the hospital trains now in use in Europe. It has a service or combination surgical car, which is in itself a thoroughly equipped operating room, six cars for patients, one standard Pullman, a combination baggage and library car and a kitchen.

RED CROSS BASE HOSPITALS FUND.—On Sept. 2 the total of the Massachusetts Red Cross Base Hospitals Fund reached the amount of \$81,745.25.

## NEW ENGLAND NOTES.

THE WEEK'S DEATH RATE IN BOSTON.—During the week ending August 26, 1916, there were 238 deaths reported, with a rate of 16.32 per 1,000 population, as compared with 201 and a rate of 13.94 for the corresponding week of last year. There were 55 deaths under one year as compared with 41 last year, and 63 deaths over 60 years of age against 42 last year.

During the week the number of cases of principal reportable diseases were: Diphtheria, 42; scarlet fever, 12; measles, 23; whooping cough, 19; typhoid fever, 5; poliomyelitis, 9; tuberculosis, 47. Included in the above were the following cases of non-residents: Diphtheria, 13; scarlet fever, 3; typhoid fever, 1.

Total deaths from these diseases were: Measles, 3; tuberculosis, 20; poliomyelitis, 6. Included in the above were the following deaths of non-residents: Tuberculosis, 3; poliomyelitis, 1.

**Obituaries.**
**WARREN FISHER GAY, M. D.**

DR. WARREN FISHER GAY died suddenly at his home in Boston, August 26, 1916, at the age of fifty years. The son of Dr. George H. Gay, one of the surgeons to the Massachusetts General Hospital, he was born in Swampscott, July 24, 1866, and was educated at the Boston Latin School and at Harvard College where he was graduated A. B. in 1890. Receiving his M. D. from Harvard Medical School in 1893, he was a house officer at the Massachusetts General Hospital, joining the Massachusetts Medical Society at this time and settling in practice in Boston, at the close of his service. He became assistant surgeon to the St. Elizabeth's Hospital and to the Boston Dispensary, and later was on the visiting staff of the Massachusetts Women's Hospital and assistant orthopedist to outpatients at the Massachusetts General Hospital. He was a member of the Boston Medical Library, Winslow Lewis Lodge, A. F. A. M., St. Bernard Commandery, Knights Templar, Harvard Musical Association, New England Historic Genealogical Society, Society of the Colonial Wars and the Bostonian Society, and he belonged to these clubs: Tennis and Racquet, Harvard, University, and Harvard Club of New York.

On June 8, 1904 he married Ellen Freeman Stiekney, daughter of Dr. Josiah and Elizabeth Stiekney, who with an only son, George Henry Gay, survives him.

**ERNEST WATSON CUSHING, M. D.**

DR. ERNEST WATSON CUSHING died at his home in Boston, August 27, 1916, aged 69 years. The son of Thomas and Elizabeth Baldwin Cushing, he was born in Boston, January 17, 1847, was educated at Chauncy Hall School, of which his father was principal, and at Harvard College, receiving his A. B. in 1867. After spending two years at the Harvard Medical School he went to New York and took his M. D. from the College of Physicians and Surgeons of Columbia University in 1871. He studied abroad and while in Vienna, in the winter of 1873, married there, Maria von Ralenowski, returning to Boston the following year to settle in practice. At first he made a specialty of diseases of the nose and throat and he was connected with the Murdock Hospital on Huntington Avenue. From 1887 to 1903 he edited the *Annals of Gynecology and Pediatrics* and in 1890 translated August Martin's textbook on the diseases of women, becoming professor of gynecology at the Tufts College Medical School in 1894 and holding the position until 1913, when he became professor emeritus. The additional title of professor of abdominal surgery at Tufts was given him in 1897 and Tufts conferred an LL.D. upon him the next year. He was a founder of the Women's Charity Club Hospital, now the Massachusetts Women's Hospital, and was its chief surgeon from its inauguration until his death. He also established a private hospital near at hand to the Massachusetts Women's Hospital and there did a large amount of abdominal surgery.

Dr. Cushing was a member of the American Gynecological Society, the American Medical Association, the Massachusetts Medical Society, having been retired only last June, a fellow of the American College of Surgery and a trustee of the Robert B. Brigham Hospital from its inception. He was possessed of a retentive memory and was an accomplished linguist. He is survived by his widow and five daughters.

**Correspondence.**
**IS IT WORTH WHILE?**

Mr. Editor:

Some years ago, more than enough for the interest if not for the recollection to have been erased from the memory of all but a small minority of the Massachusetts Medical Society, there was a tempest. From little heated active enough to excite a good deal of attention in the medical world as well as in the lay press.

Reminiscences of this abolition may be found applicable to some more recent changes which have been in the literature of a wider world.

I refer to the expulsion of several members from the older and larger Massachusetts Medical Society. The separation was accomplished with the best of good feeling, not hurting the victims, but upsets not even their best

mgs, pleasing the upholders of an ideal purity among the regulars and getting for that more conservative body a reputation for bigotry which it did not deserve and which it took years to outgrow.

These years have shown that homeopathic practice has been one among many means of disseminating more rational therapeutic views with but little reference to theories and not much more except business and perfunctory, to the name of the sect. In short, homeopathy has done a little good and some little harm in the progress of rational medicine; but rational medicine has made its steady advance with the general progress of biologic science, made practical by an ever increasing host of workers.

The official edicts of scientific societies are registrars of opinion rather than the leaders thereof. Not even high-sounding names of specialties—so easy to compound with the aid of a Greek dictionary—testify to any authoritative expression of opinion unless they have back of them the reputation and character of members with standards varying with their personalities. They are useful only as a crude classification.

Recently a multitude of utterances in professional and popular journals, based upon growing discontent with the present status of medical practice, have been brought to a focus in articles by a brilliant and candid member of this society and called out the reprobation thereof. The feeling was said to have been so strong as to have led to talk of expulsion. Fortunately this extreme action was not taken and it is to be hoped that the long vacation from committee meetings and perfunctory oratory will allow the effervescence to subside and that the time-honored teapot will continue to hold its residuum of truths only partly bitter and in part salutary. The righteous indignation against unkind sarcasm and unfair representations may well be left for cooler judgment and the effacing hand of time, while the society combines its efforts with those of the national profession of the United States and the intelligent laity in taking advantage of the useful suggestions.

These are not only not visionary or wild, but are in daily practice where circumstances are favorable. The group system of treatment is daily and extensively in practice in large hospitals,—is, in fact, indispensable. No intelligent hospital practitioner fails to feel the immense advantage, indeed the necessity, of being able to call upon his specialist colleagues in cases which he realizes do not belong to him, and no private practitioner who wishes to do his full duty to his patient does not regret that he cannot extend these advantages to persons of moderate means. One of the suggestions of Dr. Cabot's paper is to call attention or make practical the application to a large class without sending them on a tedious and expensive round of calls almost prohibitory to a large proportion of the community. It requires, however, but little ingenuity to suggest that combinations to accomplish these ends are fully within the scope of friendly cooperation.

Whether my colleagues, leading men in their specialties, who used to sit in their crowded clinics treating commonplace granular lids, plugged Eustachian tubes, hypertrophied tonsils, made more or less money than they would have accumulated by sitting in solitary state waiting for a stray millionaire, I cannot say, but these men earned the esteem of their fellows, which I sincerely trust profited them in the end.

The pessimists will say that we were all actuated by low and mercenary motives. I suppose, being human and cherishing mundane ambitions, we hoped to succeed, but there were some who, without making any pretence to absolutely disinterested philanthropy or general charity, were glad to drudge in these positions without immediate recompense. I speak of what I have seen, not of that of which I am any but a very small part, but I believe the best class of young men beginning the study of medicine are actuated by as high and worthy motives as those of the same class who are entering any career upon which they look as their professional life work. Medicine is too vast a

field to deny to any honest worker unlimited scope for scientific inquiry, and the practical side of it is worthy the devotion of the keenest intellect and of the most genuine good sense and good feeling.

Systematic social service, as incorporated in routine hospital work, is indeed a happy thought. Poverty and business embarrassments have long been recognized as factors of great importance in the development of many diseases, especially the psychic. Nobody can find fault with him who promotes the relief of these conditions in or out of hospitals. "Business efficiency" is most usefully promoted according to the tact of the promoter or the intelligence and good sense of the ward.

But the despised general practitioner has known these things for many generations and acted upon them in his crude way as opportunity has offered.

Larger questions than those merely of good taste, kindness of feeling, and professional courtesy are involved in the propriety of an official organization stamping its approval, or the reverse, upon the utterances of individual members. Such societies may take on in the eyes of the intelligent classes a certain responsibility greater than they deserve, but are more likely, on the other hand, to be looked upon with an indifference which under certain circumstances is almost criminal. It is not well for them to put themselves in any position which will deprive themselves of their due and proper influence on the right side.

Within its limits the aggrieved member has always the privilege of reply and any unjustly maligned class has usually no difficulty in finding spokesmen. Allegations of general incompetence can be met either with excuses and explanations or, on the other hand, with a "tu quoque" argument likely to become promptly an unseemly scandal. But an airing of medical ethical disputes involving delicate points of advertising is a direct play into the hands of those who can employ all the resources of the law in defeating that scourge under which the American people more widely, publicly, indecently, and ignorantly and criminally suffer than any other supposedly civilized community.

If the Massachusetts Medical Society could be reasonably accused of any wavering or half-hearted pursuit of any special form of vice, is it not certain that it would be claimed at once as favoring the moral concession, that we should be said to be lowering moral standards, abandoning the legal campaign against poisonous drugs, against criminal abortion, indecent and immoral literature, and bringing the pages of many of our medical journals to resemble indistinguishably those of lowest commercial types? It is true that problematic truths should be brought forward with circumspection, but public reprobation should not be wasted too easily on questions of etiquette and taste.

It seems to be impossible to eliminate the criminal practitioner. Nothing that medical societies can do is of any value except in upholding the strong arm of the law. Even the ignorant ignoramus must be gently, if firmly, dealt with. The friendly association of the better class into groups, the "team work," the good feeling of professional brotherhood not dependent solely on pecuniary relations are undoubtedly steps forward in purging the community of quackery.

But how much is surgery helped forward by the proclamation that there are men who do not know a cancer and who may, therefore, put off the saving diagnosis, or, on the other hand, be tempted to do an unnecessary operation for the sake of the fee? Is it not better that such men should learn, as they may easily do, that their more experienced neighbors would gladly help them for moderate fees or none at all, than that they should be publicly stigmatized as ignoramus? Is not the crudest cancer quack made more sure of his prey by the misrepresentations of the helplessness of his victims, or, on the other hand, the over-enthusiastic operator more likely to be stayed by the thought of the revision he may have to undergo at the hands of his more cautious and kindly senior?

ROBERT T. EDGS, M.D.

### Address.

## THE PORTRAITS OF FLORENCE NIGHTINGALE.\*

By MAUDE E. SEYMOUR ABBOTT, B.A., M.D.

McGill University, Montreal.

### INTRODUCTORY.

IT is nearly three quarters of a century since the name of *Florence Nightingale* first thrilled through Europe, plunged in the horrors of the terrible Crimean War. The details of her great and beneficent achievement have been forgotten by many, and in their full extent, indeed, have only been known by very few. Yet her name remains as a household word among us, breathing always the charm diffused by a life consecrated to high ideals, and symbolizing to us the power to move mountains of the passionate womanly sympathy, discerning judgment, and magnificent organizing genius, which together made her at once the Crimean heroine and the great reformer of military hygiene of the Victorian Age. Today we are again plunged into a war which has become even more terrible than any in the past, in consequence of the refinements of so-called civilization as applied to methods of modern warfare. But we have to thank the stream of military reform that set in after the Crimean crisis, so largely initiated and directed by the influence of Miss Nightingale,

that the care of the soldiers—wounded, sick, or well—has been placed at the present day on a very high plane of efficiency.

In view of the immensity of detail in such a life as that of Florence Nightingale, a complete account is impossible here. The most that can be attempted is a brief outline of those events that led up to, and followed the great Crimean climax, which revealed her to the admiration and affection of a grateful humanity. For further detail, those who are interested should consult the splendid *Life of Florence Nightingale*, by Sir Edward Cook, issued in two volumes, in 1913, by MacMillan and Company, London. The appearance of this book, from which the materials for this little sketch are drawn, has been an event in biographical literature. Based upon a thorough study of a mass of written records, including Miss Nightingale's own diaries and voluminous correspondence and many other papers, official and otherwise, not previously laid open to the public, it for the first time presents her story fully and fairly to the world, without sentimental exaggeration, but with the force of actual recorded facts. The story of the "Crimean Muddle," as the situation she was called upon to cope with in the East was picturesquely called, is told with fairness and discrimination, and the history of her activities, both then and in her subsequent life, is accurately detailed. As a result, we find the Florence Nightingale of our traditional knowledge replaced by a somewhat different, but a more human, and, we venture to think, a much greater character—one in whom the self-devotion and passionate tenderness of heart toward

\* Adapted from an Address on "The Work of Florence Nightingale and Medical Units in Active Service Today," delivered before the Harvard Historical Club, December 7, 1915.

the distressed, for which she has always been immortalized, were combined with an unswerving singleness of aim, a wide clarity of judgment, and immense powers of organization and execution that initiated and carried out far-reaching reforms. Her story, as here learned, is not alone that hackneyed theme, familiar to us all, of a gifted and gentle lady, who, moved with patriotic pity, braved the dangers of the seat of war for the sake of helping the distressed soldiers of a beloved Queen, and who became thereafter the popular heroine of the Victorian Age. The secret of her immense popularity and of the lasting greatness of her name has had a more logical foundation and a deeper root than could have been possible from the fruits of any single action. For in this case, as so often, *vox populi vox Dei est*.

From this new biography we learn that her life before that Crimean climax was one long struggling preparation and battling through of the many barriers raised alike by social prejudice and domestic affections towards the vocation that she felt was hers, though she knew not how or when it might come to her, but which, when it came, found her ready, with prejudices defeated, expert training secured, spiritually and mentally waiting for one of the great medical and military crises of the nineteenth century, that was to be hers to control and to subdue. Nor, after the crisis in the East was over, did she subside into the gentle inaction of an invalid chamber, as has been popularly thought, but from that chamber, battling with the physical illness that remained after her exertions in the Crimea, and that threatened her life many times, she proceeded unflinchingly to the solution of those many pressing problems by which medical science was revolutionized by her in various directions.

Had it not been for the absolutely Herculean labors of Florence Nightingale, invalidated in body, but of indomitable will, after her return from the Crimea, the terrible lessons of the war would have remained unlearned by the British nation, and the great reforms in the hygiene of the British army, sanitary science both in the East and West, hospital construction, and last but not least, in the profession of the gentle art of nursing,—reforms which she instituted, organized, and actually dictated to Court and Ministers alike,—would not have been carried out, and the many wrongs she righted would have remained for the sufferings of a later generation to retrieve. In the face of her prolonged illness, the heroism that struggled and won success for those reforms was on a higher plane than that by which she won the nation's praise at Scutari and Balaklava.

It is this new and immensely heroic presentment of her genius, so evident now that the true story of her life is unveiled to us, that I would endeavor to reflect here. In the words of a recent essayist, the Crimean episode, truly seen,

is only an incident in her career. Her title to rank among the great figures of history would have been as unchallengeable without that tremendous chapter. For her work was not passing, but permanent; not incidental, but fundamental.

#### THE PORTRAITS.

The series of portraits, which form an illustrative basis for this article, have been drawn from various sources, which are acknowledged below each. The writer's thanks are also due to the late Mr. J. B. Learmont, who made a collection of Nightingale memorabilia, and presented several of the fine engravings reproduced here, to various institutions in Montreal; to Miss Helen Desbrisay of the Canadian Nurses' Association for much valuable information; and especially to Dr. Harvey Cushing, to whose interest and through whose kind coöperation the publication of this article in its present form is due.

In the following paragraphs an attempt is made to group, under the periods in which these various portraits fall, a short biographical outline of the main facts, or rather factors, in the development of Miss Nightingale's character and work, and of their far-reaching results.

#### I. THE CHILDHOOD OF FLORENCE NIGHTINGALE.

(1820-1835. PLATES I AND II.)

Florence Nightingale was born in Florence, Italy, in the year 1820, during a winter's sojourn of her parents there. One of two only daughters of wealthy parents, she was brought up in all the luxurious refinement of the best type of English home, in the midst of a large and affectionate family connection, in an environment enriched by all the intellectual advantages and the happiness that such circumstances could bring. Born, as it may be said, a democrat, she quickly learned to discount the importance of these things in themselves, and yet her life was colored throughout by these early relations, which gave her, in the wide experience of suffering and distress that came to her in later years, a sense of proportionate values, and a capacity of taking herself and others for granted, that was one of the elements in her power, and that could probably have come to her in no other way. The rich English scenery, too, in which she lived throughout her childhood and girlhood days, and in which she revelled consciously, even as a little child, must have sunk deep into her observant and sensitive nature, and been to the great spiritual powers lying dormant there, as springs of water in a thirsty land. For there are few more beautiful homes and surroundings in England than the estates of Lea Hurst in Derbyshire, and Embley in Surrey, on which, with his family, Mr. Nightingale passed alternately the winter and summer months of every year.

The two sisters were the objects of much ten-

der personal care from their parents. Mrs. Nightingale was a woman who accepted and adhered strictly to the religious and social conventions of her day, but, within their limits, she was prompt and generous in the exercise of a philanthropy that devolved as a duty upon an Englishwoman of her means and position.

her childish diaries and letters contain naive comparisons and comments. She was a healthy child, fond of a frolic, and not free from unregenerate impulses towards unsympathetic governesses, yet, on the whole, serious-minded, and a little self-absorbed, with a tendency to introspection that sometimes verged upon the

FIGURE 1. MRS. NIGHTINGALE, AGE 40. (By J. M. W. Turner.)

From a portrait in the possession of Mrs. C. C. Nightingale, daughter of Mrs. Florence Nightingale.

Both her daughters were early permitted to share in their mother's solicitude for the poor of their father's estate, and to accompany her on errands of help among them. Such activities appealed especially to Florence, who quickly revealed her innate sympathy for the sick, philanthropic bent, and deeply religious nature. The contrast between the lot of rich and poor struck her then, as it continued to do with increasing force throughout life, as an incongruity, and

morbid, and an indication of weakness of her powers, that arose partly out of a conscientious knowledge of her own position, and partly from a natural sympathy, amounting almost to self-consciousness.

Her love for the poor was very strong, and she had a successful career in the nursing of the sick or well. The story of the injured soldier, long afterwards famous, was first told to her, and she was the first to suggest that he should be

broken paw, and which she tended under the guidance of the vicar, all one long summer day, until the prospect of healing was assured and the delighted shepherd acknowledged his right to live, is almost too hackneyed to repeat. But it is a true story, and is of interest, because it is intensely characteristic of a little girl who, many years later, refused to give up the lives

wonders if the adoring affection in the eyes of the gentle collie equalled the gratitude in the hearts of those poor wounded men!

Like many of his circle, for he belonged to that interesting Unitarian group among whom the Martineaus were so prominent, Mr. Nightingale held views on the higher education of women that were far in advance of his time.

PLATE II. FLORENCE NIGHTINGALE AND THE INJURED COLLIE DOG.

From an engraving in the possession of Miss White, Assistant Superintendent of the Royal Victoria Hospital, Montreal.

of the five Crimean soldiers who were pronounced "too far gone to be operated on." "Will you give me these men to do as I like with?" she asked of the surgeons as they turned away. And, the necessary consent obtained, she sat all night through beside them, tending their wounds and supporting them with food and stimulant, with such success, that when morning came, the surgeons, with surprised relief, were able to carry out what would earlier have been a useless task. One

He personally supervised the education of his daughters, himself teaching them, as they grew older, modern languages and classics, European and Constitutional History, and even higher mathematics. They wrote essays and analyzed philosophical treatises, pursuing much the same course of study, under his tutorship, as would be followed now for a university degree. Florence was an ardent and laborious student, arising often at four in the morning to carry out her preparations, and, as Sir Edward Cook

remarks, to her father's guidance in these ways she was undoubtedly indebted for the mental grasp and power of intellectual concentration that distinguished her work in later life.

Conscientious to a degree, imbued with a feeling of responsibility and a religious sense of self-dedication that developed in her very early years, absorbed in a round of studies, duties, and pleasures, provided by her wise yet indulgent parents, Florence Nightingale grew from an engaging child into the "girl of sixteen of great promise" that a contemporary letter describes.

## II. GIRLHOOD AND EARLY WOMANHOOD.

(1835-1853. PLATES III, IV, V, VI.)

In 1837, when his younger daughter was seventeen, Mr. Nightingale took his family to the Continent, and eighteen delightful months were spent in leisurely travel through France, Italy and Switzerland. Everywhere the best social, artistic, musical, literary and political circles were open to them, and they entered heartily into the complex foreign life about them. The tour ended with a winter in Paris, where, in the brilliant salons of their friends, the two charming girls discovered themselves both attractive and attracted. Freed from the shyness that had troubled her, Florence found she had social gifts of a high order, and confesses in her diary that the last temptation she had to overcome, before she was free to interpret that insistent inner call, was a "desire to shine in society."

PLATE III. FLORENCE NIGHTINGALE AS A CHILD.

From a drawing by Sir Hilary Burton. Letter in Sir Edward Cook's *Life of Florence Nightingale*.
